

The University of Toronto
Chemical Library

Presented
to

The University of Toronto Library
by

William Lash Miller, B.A., Ph.D., C.B.E.

Professor Emeritus of Physical Chemistry
for

A Departmental Library to be under

the control of the Professor of

Chemistry according to the conditions

set out in a letter from the Librarian

of the University dated March 21st

1938.

Digitized by the Internet Archive

THE JOURNAL

OF THE

111
Society of Chemical Industry.

VOL. XXXVI.--1917.

373667
11 12 39

LONDON:
VACHER & SONS, LTD.,
GREAT SMITH STREET, WESTMINSTER, S.W.1.—56520.

The Society of Chemical Industry.

LIST OF PAPERS PRESENTED TO THE SOCIETY AND PUBLISHED IN THE JOURNAL DURING 1917.

N.B.—The words within () indicate the Section of the Society (if any) before which the paper was read and the issue of the Journal in which it appears.

	PAGE		PAGE
Adam, A. T. Wire drawing. (Edinburgh, Mar. 15)	241	Burrell, B. A. <i>See</i> Fairley, T.	113
Alcock, F. <i>See</i> Coombs, F. A.	188	Campbell, L. E. Preliminary note on the natural coagulation of the latex of <i>Hevea brasiliensis</i> . (Mar. 15)	274
Alexander, J. The importance of "impurities" (New York, Jan. 15)	7	Carpenter, C. Presidential Address. (July 31)	712
Anderson, G. W. Detection of hydrocyanic acid. (Feb. 28)	195	Challinor, R. W., and A. R. Penfold. Chemical examination of the oil from the Australian dugong. (Sydney, Feb. 28)	192
Anderson, H. S. <i>See</i> Wilkie, J. M. ..	272	Clayton, W. Modern margarine technology. (Liverpool, Dec. 15)	1205
Annan, J. G. Motor spirit. (Edinburgh, Mar. 15)	243	Collins, S. H. A portable plant for the distillation of wood. (Newcastle, Jan. 31)	68
Ardern, E. The activated sludge process of sewage purification. (Manchester, Jan. 31)	65	Colver, E. De W. S., and E. B. R. Prideaux. Estimation of nitrotoluenes. (Aug. 15) and E. B. R. Prideaux. The stannous chloride reduction method for estimating nitrotoluenes. (Nottingham, May 15)	856 480
A résumé of the present position of the activated sludge process of sewage purification. (Annual Meeting, July 31)	822	Coombs, F. A., and others. Comparative tests with mangrove and wattle barks. (Sydney, Feb. 28)	188
Armstrong, H. E. Our need of a national fuel and power policy. (Nottingham, Feb. 28)	182	Coste, J. H. The absorption of atmospheric gases by water. (London, Aug. 15) ..	846
Babington, F. W., and A. Tingle. The standardisation of decinormal sulphuric acid. (Canadian, Dec. 15) ..	1203	Day, F. W. F. <i>See</i> Eaton, B. J.	1116
Bacon, R. F. Some present-day technological problems. (New York, Jan. 15)	9	De Cew, J. A. The function of colloidal chemistry in paper making. (Canadian, Apr. 16)	357
Baker, J. L. The use of brewers' yeast in bread-making. (London, July 31) ..	836	De Vries, O., and H. J. Hellendoorn. On the permanent set of rubber. (Dec. 31)	1258
Barker, M. F. <i>See</i> Fox, J. J.	842	Eaton, B. J. New researches on the variability of plantation Para rubber. (Dec. 15)	1217
Beckett, E. G. A laboratory gas meter. (Glasgow, Jan. 31)	52	and F. W. F. Day. Further experiments on the combined sulphur content of slow and fast vulcanising plantation Para rubber. (Nov. 15)	1116
Boswell, P. G. H. Sands used in metallurgical practice, with comparative notes on those used in glass manufacture. (Annual Meeting, July 31)	753	and F. W. F. Day. A preliminary investigation on the estimation of free and combined sulphur in vulcanised rubber, and the rate of combination of sulphur with different types of plantation Para rubber. (Jan. 15)	16
Bottomley, F. Fused silica. (Newcastle, June 15)	577	Espenhahn, E. V. Some notes on ammonium thiosulphate-polythionate solutions. A contribution to liquid purification of coal gas. (May 15)	483
Bradley, A. B. A note on the corrosion of steel water pipes. (Oct. 31)	1071	Fagan, T. W. <i>See</i> Lauder, A.	1069
Brightman, R. The action of nitric acid on castor oil. (London, Sept. 29)	984		
Browning, K. C., and M. Parthasarathy. Note on ghee. (Feb. 15)	118		
Brownsdon, H. W. Cartridge brass. (Annual Meeting, July 31)	794		
The use of nitre cake as a substitute for sulphuric acid in the pickling of annealed brass. (Birmingham, June 15)	575		

	PAGE		PAGE
Fairley, T., and B. A. Burrell. Note on a dangerous oil used in a woollen mill. (Yorkshire, Feb. 15).....	113	Lessing, R. New method of extracting the vaporous constituents from coal gas. (London, Feb. 15)	103
Fletcher, J. E. On the superheating of slags and metals during refining, smelting, and alloying operations. (Annual Meeting, July 31)	796	Lidstone, F. M. A mercurial viscometer. (Nottingham, Mar. 15)	270
Fox, J. J., and M. F. Barker. Determination of phenol in commercial cresylic acid. (London, Aug. 15).....	842	Errata	317
Foxwell, G. E. Some future lines of advance in coking practice. (Yorkshire, May 31)	525	Lockett, W. T. Experiments relating to the activated sludge process of sewage purification. (Manchester, Mar. 15) ..	264
Gilechrist, D. A., and H. Louis. Basic slag as affecting agricultural development. (London, Mar. 15)	261	Louis, H. The economics of coal production. (London, Dec. 15)	1209
Grigioni, J. L. See Hobbsbaum, I. B.	52	See Gilechrist, D. A.	261
Grossmann, J. Manufacture of nitric acid from nitre cake. (Manchester, Oct. 15, Nov. 30)	1035, 1161	Lusk, G. Food values. (New York, May 31) ..	524
Hancock, W. C., and W. E. King. Some observations on the texture of fire-clays. (Annual Meeting, July 31) ..	747	McCowan, W. See Twiss, D. F.	692
Hay, F. W. Patent law in relation to British chemical industry. (London, Nov. 30) ..	1151	Mackey, W. McD., and H. Ingle. The oxidation of oils in presence of soluble metallic catalysts. (Yorkshire, Mar. 31)	317
Hellendoorn, H. J. See De Vries, O.	1258	Maclaurin, R. Low temperature carbonising and some products. (Glasgow, June 30) ..	620
Hembrough, E. See Richmond, H. D.	317	McLellan, B. G. Note on boiler corrosion. (Yorkshire, Aug. 15)	853
Hitchman, F. G. See Richmond, H. D.	273	Mann, E. W. The future of the fine chemical industry. (Annual Meeting, July 31) ..	830
Hobbsbaum, I. B., and J. L. Grigioni. Production of nitrate of soda in Chile—past, present, and future. (London, Jan. 31)	52	Mansbridge, W. The modern whale oil industry. (Liverpool, Apr. 16)	362
Hollins, C. Application of the Gutzeit test to works' determination of arsenic. (Liverpool, June 15)	576	Maxted, E. B. The synthesis of ammonia, and the oxidation of ammonia to nitric acid. (Annual Meeting, July 31)	777
Ingle, H. Theory of the action of "driers." (Yorkshire, Mar. 31)	319	Medofski, S. See Radcliffe, L. G.	628
See Mackey, W. McD.	317	Moore, H. The spontaneous ignition temperatures of liquid fuels for internal combustion engines. (Manchester, Feb. 15)	109
Ittner, M. H. The Twitchell process in the soap and candle industry. (New York, Feb. 28)	181	Parker, R. G. The estimation of free sulphur trioxide in fuming sulphuric acid by titration with water. (July 16)	692
Johnson, F. Electrolytic copper. (Annual Meeting, July 31)	803	Parthasarathy, M. See Browning, K. C.	118
Jones, D. T. The thermal decomposition of low temperature coal tar. (Glasgow, Jan. 15)	3	Peachey, S. J. Catalytic acceleration of the vulcanising process. (Manchester, Apr. 30)	424
Jones, F. B. See Spielmann, P. E.	489	Organic vulcanisation accelerators. (Mar. 31)	321
Jones, R. O. Notes on the splitting of castor oil. (Liverpool, Apr. 16)	359	Vulcanisation catalysts. (Sept. 15) ..	950
King, C. A. Notes on the working of a dust-fired boiler. (Yorkshire, Feb. 15)....	114	Peile, H. Utilisation of waste heat from coke making. (Newcastle, Feb. 15)	112
King, W. E. See Hancock, W. C.	717	Penfold, A. R. See Challinor, R. W.	192
Knecht, E. Determination of the nitro-toluenes. (July 16)	694	Petrie, G. C. See Spielmann, P. E.	831
Knudsen, K. H. The removal of pitch from sulphite pulp. (Mar. 31)	324	Pickering, W. J. The calorific value of industrial gaseous fuel. (Annual Meeting, July 31)	762
Lamb, M. C. Utilisation of condemned Army boots. (London, Sept. 29)	986	Pollitt, A. A. See Radcliffe, L. G.	269
Langmuir, A. C. The Twitchell process and the glycerin trade. (New York, Feb. 28)	180	Porritt, B. D. The purchase and control of factory supplies. (Edinburgh, July 16) ..	674
Lantsberry, F. C. A. H. Constructional steels and their heat treatment. (Annual Meeting, Sept. 29)	983	The scientific needs of the rubber industry. (Annual Meeting, July 31)	789
Lauder, A., and T. W. Fagan. The utilisation of fatty acids for feeding purposes. (Edinburgh, Oct. 31)	1069	Powell, A. D. The estimation of small quantities of cobalt. (Nottingham, Mar. 15)	273
		Prideaux, E. B. R. See Colver, E. De W. S.	480, 856
		Radcliffe, L. G., and S. Medofski. The examination of acetic anhydride. (Manchester, June 30)	628
		and A. A. Pollitt. The preparation and properties of 1,3,5-trinitrobenzene. (Manchester, Mar. 15)	209
		Rai, H. The catalytic bleaching of oils, fats, and waxes. (Sept. 15)	948

	PAGE		PAGE
Rakshit, J. N. The titration and estimation of morphine with iodic acid. (Sept. 29)	989	A new acid sodium phosphate and its action upon glass, porcelain, silica, platinum, and nickel vessels. (Manchester, Apr. 30)	419
Rhead, T. F. E. Some sources of benzene and toluene for high explosives. (Annual Meeting, July 31)	764	Spence, D. Organic vulcanising accelerators. (Feb. 15)	118
Richardson, F. W. The estimation of free sulphuric, nitric, and picric acids in presence of each other. (Yorkshire, Jan. 15)	13	Spiehnann, P. E., and F. B. Jones. The estimation of xylene in solvent naphtha. (May 15)	489
Richmond, H. D., and E. Hembrough. A simple and efficient gas absorption apparatus. (Nottingham, Mar. 31) ..	317	and G. C. Petrie. Some observations on crude benzols. (London, July 31) ..	831
and F. G. Hitchman. Rapid determination of oil in malt and cod liver oil preparations. (Nottingham, Mar. 15)	273	Stansbie, J. H. The analysis of some aluminium alloys. (Annual Meeting, July 31) ..	802
Ridge, H. M. The utilisation of the sulphur contents of zinc ore. (London, July 16)	676	Stelling, A. <i>See</i> Coombs, F. A.	188
Rintoul, W. The preparation of chemicals for laboratory use. (Glasgow, Mar. 15) ..	247	Steuart, D. R. The brown coal distillation industry of Germany. (Edinburgh, Feb. 28)	167
Robertson, G. S. The rate of reversion of mixtures of superphosphate with basic slag and rock phosphates. (London, June 30)	626	Stevens, H. P. The natural accelerator of Para rubber. (Apr. 16)	365
Rowell, H. W. Schemes for co-operative industrial research. (Annual Meeting, July 31)	814	The vulcanisation of rubber by agents other than sulphur. (London, Feb. 15) ..	107
Some principles of industrial research organisation. (Annual Meeting, July 31)	815	Tingle, A. <i>See</i> Babington, F. W.	1203
Russell, E. J. Artificial fertilisers—their present use and future prospects. (London, Mar. 15)	250	Tookey, W. A. The composition of power gases. (London, Mar. 31)	309
Waste land and agriculture. (Nottingham, Dec. 31)	1251	Tromp, F. J. Steam distillation. (Mar. 15) ..	276
Sachs, A. P. The estimation of nitrogen in nitro compounds. (Aug. 31)	915	Turner, T. The local metallurgical industries. (Annual Meeting, July 31)	793
Scott, E. K. Economy of acids in metal trades. (Annual Meeting, July 31) ..	810	Twiss, D. F. The chemistry of vulcanisation. (Annual Meeting, July 31)	782
The manufacture of synthetic nitrates by electric power. (Annual Meeting, July 31, Aug. 31)	915	Vulcanisation catalysts. (Oct. 31) ..	1072
Seligman, R., and P. Williams. Further notes on the action of acetic acid on aluminium. (London, Apr. 30)	409	and W. McCowan. A modified Soxhlet extractor. (July 16)	692
Smalley, O. The influence of arsenic in brass. (Newcastle, Apr. 30)	429	Vakil, K. H. Cotton seed products. (Manchester, July 16)	685
Smith, A. T. Some problems confronting the chemical industry. (Liverpool, Nov. 15)	1111	Walter, C. M. Recent developments in the industrial application of town's gas. (Annual Meeting, July 31)	769
Smith, E. W. Industrial fuel from gas works. (Annual Meeting, July 31)	758	Watkin, H. Chemical laboratory porcelain. (Annual Meeting, July 31)	749
Smith, J. H. The constitution of the alkali phosphates, and some new double phosphates. (Manchester, Apr. 30) ..	420	Wilkie, J. M., and H. S. Anderson. Soluble filters and filtering media. (Nottingham, Mar. 15)	272
The estimation of phosphoric acid and phosphates by alkaometric methods. (Manchester, Apr. 30)	415	Williams, P. <i>See</i> Seligman, R.	409
		Wilson, L. P. The artificial silk industry. (Annual Meeting, July 31)	817
		Winnill, T. F. The low temperature distillation of inferior coals. (Yorkshire, Aug. 31)	912
		Wood, J. W. Note upon the rate of softening by the lime-soda process. (Yorkshire, Dec. 31)	1256
		Woodmansey, A. The effect of various "thinners" on the drying of linseed oil, and the action of driers on turpentine. (Yorkshire, Dec. 31)	1253

Journal of the Society of Chemical Industry.

VOL. XXXVI.—1917.

NAME INDEX.

N.B.—In this Index (P) indicates that the matter referred to is an abstract of a patent.

Where the letter *r* follows the number of a page, it indicates, in the case of a patent, that a reference only to a previous patent appears on that page; in the case of articles other than patents, the title only of the article will be found on such pages.

The titles of new books are given within quotation marks.

		PAGE
A		
Aaron, A., and others. Leather; Process of treating — for gloves (P)	895	
Aarts, C. J. G. Zinc sulphide; Process for oxidising — (P)	952	
Aarts, J. G. Ammonia; Production of — from coke (P)	136	
Carbonising furnaces, or furnaces for reducing ores (P)	1000	
Abady, J. Patent law in relation to British chemical industry. Discussion	1159	
Abderhalden, E. Yeast; Behaviour of — towards different sugars at various concentrations, and influence of addition of amino-acids on fermentation	1283	
and A. Fodor. Enzyme action. Enzymic degradation of polypeptides	663	
Abdes, E. Stones; Covering natural and artificial — with a metallic coating (P)	292	
Abelin, L. <i>p</i> -Sulphomethylaminophenylarsinic acid	1028	
and S. Lichtenstein-Rosenblatt. <i>p</i> -Aminophenyl salicylate; Manufacture of a bromo-derivative of — (P)	668	
Abelous and Aloy. Oxidation and reduction; Biochemical phenomena of simultaneous —	1024	
Abortillery Works, Ltd. See Cole, J. H.	930 <i>r</i>	
Abraham, H. Roofing material (P)	719	
Abrams, D. A., and O. E. Harder. Sands for mortar; Colorimetric determination of organic impurities in —	718	
Acetylene Illuminating Co., Ltd., and A. Stephenson. Gases; Storing of — under pressure (P)	25, 704, 860 <i>r</i>	
and R. J. McL. Whibley. Gases under pressure; Storing of — (P)	704	
Acheson, E. G., and Acheson Corporation. Deflocculating solid materials (P)	586	
Acheson Corporation. See Acheson, E. G.	586	
Acléries Réunies de Burbach-Eich-Dudelange. See Vereinigte Hüttenwerk Burbach-Eich-Dudelangen A.-G.		
Ackermann, E. Milk; Analysis of —	1025	
Acree, S. P. See Judd, R. C.	448	
See Luba, H. A.	101	
See Mangum, A. W.	730	
See Pieper, E. J.	638, 865	
See Smith, H. K.	448	
Actien-Ges. für Anilinfabrikation. Betaine; Manufacture of — from molasses (P)	473 <i>r</i>	
Disazo dyes (P)	331 <i>r</i>	
3-Nitrocarbazole and its halogen derivatives; Production of — (P)	542	
Orthohydroxynitroazo dyes (P)	449 <i>r</i>	
Sodium thiosulphate or residues from manufacture of sulphur dyes; Obtaining sodium sulphate and sulphur from — (P)	647	
Sulphur dye-stuffs; Manufacture of — (P)	131 <i>r</i> , 211	
Tetrakisazo dyestuffs; Blue — (P)	1174	
Trisazo dyestuffs (P)	211	
Act.-Ges. für Chem. Prod. vorm. H. Scheidemandel. See under Scheidemandel.		
Akt.-Ges. Cillander. Cotton fabrics; Production of transparent and wool-like effects on — (P)	289	
Akt.-Ges. für Zink-Industrie vorm. Grillo. See under Grillo.		
Adam, A. T. Wire-drawing	241	
Adam, H. R. Copper-gold-silver ore; Treatment of — at the Falcon Mine (Rhodesia)	220	
Adam, M. A. Cellulosic materials; Chemical treatment of — (P)	544	
Adam, W. G. Ammonium sulphate; Manufacture of — (P)	1007	
Oil-washing for recovery of benzene and toluene from coal gas	331	
Adams, A. H. See Armstrong, P. A. E.	1192	
Adams, E. W., and S. G. W. Farthing. Coated fabric (P)	1044	
Adams, H. Centrifugal pulveriser (P)	581	
and Adams Mining Machinery Corporation. Coal; Non-attrition process and apparatus for washing and sorting — (P)	636	
Adams, J. R. See Kelley, G. L.	1011	
Adams, R., and C. H. Beebe. Cyanamides; Synthesis of amidines from —	100	
and L. F. Weeks. Oxalyl chloride; Action of — on primary, secondary, and tertiary alcohols	46	
Adams, W. H. Waterproof fabric and coating (P)	959	
Adams Mining Machinery Corporation. See Adams, H.	636	
Adanti, G. Zinc phenolsulphonate; Volumetric determination of —	1194	
Addicks, L. Copper concentrates; Possibilities in wet treatment of —	35	
Copper refining; By-products in electrolytic — ..	1051	
Copper refining; Current density in electrolytic — ..	505	
Copper refining; Current efficiency in — ..	220	
Copper refining; Impurities in electrolytic — ..	966	
Addressograph Co. See Bailey, J. A.	930	
Adie, R. H. See Wood, T. B.	469	
Adkins, L. R. Liquids; Transportation and storage of — in small packages	1226	
Adler, L. Ammonia from nitrogen in brewing materials; Determination of — by the boric acid method	157	
Malt diastase; Influence of the hydrogen ion concentration on the activity of —	230	
Malts; Comparative studies on floor, drum, and box	158	
Adom, M. R. Textile fabrics; Rendering — "antique" (P) ..	709	
Aetna Explosives Co. See Flürschheim, B. J.	670	
Aggersborg, H. C. Radioactive mineral waters containing radium-precipitating acids; Preparation of — (P) ..	1047	
Aghan, W. H. Precious metals; Separating — from their ores (P)	223	
Aisen, M. N. Hydrolysed glue; Manufacture of — (P) ..	81	
Sizing and dyeing; Composition for — (P)	81	
Sizing solution and method of making it (P)	640	
Alta, A. Mineral phosphates and superphosphates; Solubility of — in organic and dilute mineral acids ..	897	
Aitken, T. W. Crucible furnaces for melting metals (P) ..	907	
Aitken, W. A. Pulp, paper, cardboard, and the like; Arrangements for heating and draining the cylinders of machines for making and treating — (P)	708	
Ajax Heaters, Ltd., and R. C. Russell. Heating water or other liquids; Apparatus for — (P)	1030	
Ajax Metal Co. See Wyatt, J. R.	1053	
Akins, R. P. See Bucher, J. W.	509	
Aktiebolaget Ingenjörerna F. Egnell. See under Egnell.		
Aktiebolaget Kolloid i Likvidation. Colloidal solutions; Production of stable — (P)	203	
Akt.-Ges. See under Act.-Ges.		

	PAGE		PAGE
Aktieselskabet Drivremmefabriken "Dana." Leather; Manufacture of a product analogous to — (P) ..	80r	Alway, F. J., and V. L. Clark. Hygroscopic coefficients of soils; Determination of the ..	40
Textile fabrics; Process for treating — for the manufacture of bolts, coverings, containers, etc. (P) ..	80	Amber Size and Chemical Co. See Fish, C. W.	870r
Albert, K., Chem. Fabr., and L. Brend. Carbon bricks and ceramic bodies containing carbon; Manufacture of — (P) ..	85	Amend, O. P. See Axtell, C. F.	609
See Schleimer, O.	145r	American Air-Liquefying Co. See Place, J. F.	84, 84
Albertson, J. M. See Evans, P. N.	472	American Alloys Co.'s Alloys (P) ..	969r
Albrecht, J. A. Artificial resin preparation for treating teeth (P) ..	31	American Chemical Paint Co. Cleaning metal for painting (P) ..	969
Albright, A. R. Methyl salicylate; Examination of —	537	American Clay Machinery Co. See Perrott, R. O.	388
Alby United Carbide Factories, Ltd., and K. Hylland. Oxygen compounds of metals or metalloids and carbonaceous substances; Manufacture of an intermediate product for use in processes based on heating together — (P) ..	138	American Encaustic Tiling Co. See Lillibridge, H. D. ...	596, 596
Alchbr Chemical Co. See Barnett, M.	456	American Gum Products Co. See Coughlin, M. F.	512
Aleck, F. See Coombs, F. A.	188	American Incandescent Heat Co. See Smallwood, A.	699
Aleck, F. H. Benzene and toluene; Some sources of — for high explosives. Discussion ..	768	American Manganese Steel Co. See Johnson, F. E.	1263
Nitre-sake; Use of — as substitute for sulphuric acid in pickling annealed brass. Discussion ..	576	American Optical Co. See Bagbee, L. W.	344
Rubber industry; Scientific needs of the —. Discussion ..	793	American Ore Reclamation Co. See Yost, F. W.	223
Aleck, W. J., and G. K. Davis. Sulphuric acid; Manufacture of — (P) ..	82	American Smelting and Refining Co. See Garr, S. R.	223
Aldrich, T. B., and C. P. Beckwith. Triblogentertiarybutyl alcohols; Derivatives of — Acetic ester of tribromo-tertiary butyl alcohol or bromotone acetic ester ..	109	See Whitehead, R. L.	146
Alessandri, L. See Angeli, A.	210	Ames, J. W., and T. E. Richmond. Manure treated with sulphur and sulphates; Fermentation of —. Changes in nitrogen and phosphorus content ..	1020
Alexander, C. M., and Gulf Refining Co. Aromatic hydrocarbons; Manufacture of — (P) ..	922	Ames, R. Sewage and other foul liquids; Apparatus for aerating — (P) ..	519, 977, 1247
Alexander, J. "Impurities"; Importance of — ..	7	Ames, R. Y. See Allen, B. J.	1274
Alford, H. C., and others. Resinous woods; Process of treating — (P) ..	80	Anchor Cap and Closure Corporation. Sterilising and preserving foods (P) ..	977, 1025
Ali, B. See Barnes, J. H.	1956	Anders, H. R., and Roessler and Hasslacher Chemical Co. Animal filaments, fibres, or threads; Process of finishing — (P) ..	212
Ali-Cohen, E. S. Vulcanisable elastic masses suitable for use as rubber substitutes; Production of — (P) ..	1140	Andersen, E. B. Ammonia; Catalytic oxidation of — ..	81
Aliva, H. L. Petroleum products, shale oils, coal tar oils, etc.; Apparatus for continuous fractionation and dephlegmation of — (P) ..	127	Andersen, E. W. Kiln for drying vegetable substances, such as copra, etc. (P) ..	463r
Allan, J. Cotton seed products. Discussion ..	691	Andersen, H. W. Impregnating woven belts and conveying bands (P) ..	451r
Allent, E. A. See Avery, W. and T. Ltd.	616r	Andersen, O. L. K. Boilers and the like; Preventing fur from depositing in — (P) ..	445
Alldays, P. W. See Alldays and Onions Pneumatic Engineering Co.	329	Anderson, A. K. Sorghum juice; Chemical changes caused by defecation of — for syrup manufacture ..	662
Alldays and Onions Pneumatic Engineering Co. Ltd., and P. W. Alldays. Annealing furnaces heated by gaseous fuel (P) ..	320	Anderson, E., and R. J. Nestell. Cement materials; Volatilisation of potash from — ..	458, 926
Allen, A. W. See Thomas, N.	593	See Nestell, R. J.	926
Allen, B. J. Fireclay and similar articles; New process of manufacturing — ..	549	Anderson, G. W. Hydrocyanic acid; Detection of — ..	195
and R. Y. Ames. Casting pottery and like articles; Process for — (P) ..	1274	Anderson, H. S. See Wilkie, J. M.	272
Allen, B. P. Electrolytic process for coating metal (P) ..	1015	Anderson, L. D., and United States Smelting, Refining, and Mining Co. Furnace-charging system (P) ..	1039
Alleo, E., and Co. See Davies, A.	690	Anderson, R. J. Ferromanganese in the iron and steel industry ..	649

SUBJECT INDEX.

N.B.—In this Index (P) indicates that the matter referred to is an abstract of a patent.

Where the letter *r* follows number of page, it indicates that a reference only to a previous patent appears on that page; or, in the case of matter other than patents, that the subject is only referred to by title.

A		PAGE
Abietic acids; Optical isomerism of the —. Schultz	1230	
Abrasive articles; Manufacture of —. (P) Urtel, and Carborundum Co.	1275	
composition containing alumina and zirconia. (P) Saunders and others	1139	
material; Manufacture of —. (P) Kalma, and Exolon Co.	718	
wheels; Manufacture of —. (P) King, and Norton Co.	85, 1019	
Abrasives; Manufacture of aluminium —. (P) Svanlers and others	1139	
Manufacture of — for cleaning and polishing. (P) N. V. West Borneo Cultuur Maatschappij	139, 157r	
Absorbent material; Suction-roll arrangements for drying —. (P) Hellström	1269	
Absorption apparatus; Simple and efficient gas —. Richmond and Hembrough	317	
of nitric acid, hydrochloric acid, and like gases. (P) Charles and Lancaster	962	
towers; Filling material for —. (P) Goodwin	1223	
towers; Packing or filling for —. (P) Oates and Robinson	1170	
towers; Packing materials for —. (P) Raschig	700	
Acacia arabica pods as tanning material in India	559	
Acer saccharum; Composition of wood of — Schorger	867	
Acetaldehyde; Manufacture of —. (P) Hibbert and others	103, 403	
Manufacture of acetic acid from —. (P) Badische Anilin u. Soda Fabr.	503	
Manufacture of — from acetylene. (P) Chem. Fabr. Rhenania, and others	1194	
Manufacture of condensation products from —. (P) Grünstein	1064	
Acetaldehyde-ammonia; Action of — on quinones. Ghosh	958	
Acetanilide; Micro-chemical identification of —. Tunmann	1238	
Acetate of lime. See under Calcium acetate.		
Acetates; Inadequacy of basic ferric acetate test for —. Curtman and Harris	979	
Acetic acid; Action of — on aluminium. Seligman and Williams	409	
Dealings in —	1249	
and ferric chloride; Constitution of compounds formed by interaction of lactal. Weiland and Kessler	135	
Influence of — on the synthetic and hydrolytic action of α -glucosidase. Bourquelot and Aubry	42	
Manufacture of —: (P) Hiltart, and Union Carbide Co.	925	
(P) Holzverkohlungs-Ind. A. G.	962	
Manufacture of — from acetaldehyde. (P) Badische Anilin u. Soda Fabr.	503	
Purification of —. (P) Gorham	214	
Steam distillation of — alone and in admixture with propionic, butyric, or valeric acid. Richmond	519	
Use of sucrose-inverting bacteria for manufacture of —. Mezzadrelli	1021	
as war material	1035	
Acetic anhydride; Examination of —: Radcliffe and Medofski	628	
Sage	667	
Manufacture of —. (P) Dreyfus	102, 611, 668	
Acetic ester of tribromo-tertiary-butyl alcohol. Albrich and Beckwith	100	
Acetone and air; Propagation of flame in mixtures of —. Wheeler and Whitaker	587	
as by-product of the soda-pulp industry: Lawrence	543	
White and Rue	383	
and calcium chloride; Compounds of —. Bagster	906	
Manufacture of — and of alcohol and yeast. (P) Bayer and Co.	1180	
Use of sucrose-inverting bacteria for manufacture of —. Mezzadrelli	1024	
Acetonitrile; Manufacture of — from acetylene. (P) Chem. Fabr. Rhenania, and others	1191	
2-Acetylaminio-2,4-dimethoxybenzoic acid; Nitration of —. Gibson and others	381	
3-Acetylaminoveratrole; Nitration of —. Gibson and others	381	
Acetylcelluloses. See Cellulose acetates.		
Acetyl compounds; Application of Duclaux's method to determination of purity of —. Richmond	520	
Acetylene; Action of anhydrous aluminium chloride on —. Gungloff and Henderson	956	
and air; Limits of complete inflammability of mixtures of —. Burrell and Ginger	955	
and air; Uniform movement of flame in mixtures of —. Howard and Sastry	1089	
Manufacture of ethylene from —. (P) Traube	569	
Manufacture of products of condensation and oxidation from —. (P) Chem. Fabr. Rhenania, and others	1191	
Storing compressed or dissolved —. (P) Allen	1000r	
Storing of — under pressure. (P) Acetylene Illuminating Co., and Stephenson	25	
Vapour pressure at low temperatures, and boiling point of —. Burrell and Robertson	711	
Acetylmethylcarbinol, a volatile reducing substance present in elder vinegar. Balcom	359	
Acetylsalicylic acid; Analysis of —. François	519	
Determination of — and of sodium salicylate in powders. Miller	1028	
Manufacture of salts of —. (P) Gerngross and Kast	473r	
Salts of —. Bouvet	612	
Achrolextrinas Eifront	468	
Acid content of fruits. Bigelow and Daubar	1025	
-proof cement; Manufacture of —: (P) Electro-chemical Supply and Engineering Co.	965	
(P) Melks, and Electro-Chemical Supply and Engineering Co.	1010r	
(P) Wedge, and Electro-Chemical Supply and Engineering Co.	594	
-resisting cement. (P) Chance and Hunt, and others ..	1237	
-resisting properties of some iron-silicon alloys. Kowalko ..	1097	
Acids; Apparatus for concentrating —. (P) Oliver ..	647r	
Automatic pulsometer for raising —. (P) Cotellet ..	124	
Concentrating —. (P) Oliver	647r	
Concentration or recovery of —. (P) Bouhon	645	
Corrosion of metals by —. Watts and Whipple	1238	
Economy of — in the metal trades. Scott	810	
Effect of — on the rotatory power of sucrose and invert sugar in presence of soluble salts. Sallard	973	
Effect of — on soil bacteria in the soil solution. Gruitz ..	605

Aluminous compounds; Treatment of —. (P) Spence and others	1177	<i>p</i> -Aminophenyl salicylate; Manufacture of a bromo-derivative of —. (P) Abelin and Lichtenstein-Rosenblatt	668
materials; Process for treating —. (P) Lawrie, and Jobbins, Inc.	888	Aminosulphonic acids; Displacement of sulphonic acid groups in — by halogen atoms. Sudborough and Lukhmalani	333
Alunite deposits in Vancouver. Clapp	29	Ammonia; Absorbing — and apparatus therefor. (P) Badische Anilin u. Soda Fabr.	386r
Extracting potash and aluminium from —. (P) Fox	455	Absorption of — by charcoal. Richardson	1098
Manufacture of alumina and potassium sulphate from —. (P) Blough and others	386	and ammonium polythionate; Reactions between —. Espenhahn	484
Manufacture of aluminate from —. (P) Hershman, and Armour Fertilizer Works	1128	ammonium polythionate, sulphur dioxide, and ammonium sulphide; Reactions between — at 100° C. Espenhahn	487
Method of treating —; (P) Cameron	1008	ammonium polythionate, and sulphur dioxide; Reactions between — at 100° C. Espenhahn	486
(P) Cameron and Cullen	1127	Apparatus for condensing —. (P) Block	138r
Allylamine. See Tetramethylaminodimethylethylcarbinyl benzoate hydrochloride.		Applications of a new reagent for separation of —. Folin and Bell	572
Amalgamating process for recovering metals from ores. (P) Kuchu	929	and benzene; Formation of aniline from — at high temperatures and in presence of contact substances. Wibaut	638
Amalgamators; (P) Lounsbury, and Mid-Continent Machinery Co.	291	and calcium; Action of — on benzene. Dumanski and Zvereva	236
(P) Tuggle, and Redemption Gold Co.	1015	Catalysts for oxidation of — to nitrogen oxides. (P) Badische Anilin u. Soda Fabr.	215r
and separators; Centrifugal —. (P) Zimmer	510	Catalytic oxidation of —. Andersen	81
Amalgams; Dental —. (P) Davis	33r	Catalytic production of —. (P) Badische Anilin und Soda Fabr.	647r
Manufacture of —. (P) Halvorsen, and Roessler and Hasslacher Chemical Co.	1211	and chlorine; Reactions between —. Dowell and Bray	711
American beers and ales; Study of —. Tolman and Riley	909	Colorimetric determination of — in urine. Folin and Bell	572
dyestuffs industry; Development of the —	992	and compounds thereof; Manufacture of —. (P) Lamb	83
Amides; Pyrogenetic decomposition of —. Bochner and others	46	Condenser for —. (P) Block	215
Transformation of nitriles into — by hydrogen peroxide. McMaster and Laugreek	305	Determination of — in soil and in liquid manure. Baragiola and Schuppli	1020
Amidines; Synthesis of — from cyanamides by means of the Grignard reagent. Adams and Beebe	100	Determination of — volumetrically, after destruction of organic matter in presence of mercury. Justin-Mueller	238
Amines, aromatic; Action of — on fatty acids. De Conno	511	distillation and tar dehydration plant; Combined —. (P) Bill and Hiller	866
aromatic; Manufacture of mono-alkyl derivatives of —. (P) Morgan	207	Extracting — from ammoniacal liquor. (P) Schuster, and British Coke Ovens, Ltd.	1272r
aromatic; Production of — and catalysts therefor. (P) Badische Anilin und Soda Fabr.	78	Extraction of — from organic refuse by destructive distillation. (P) Benton's Patents, and Benton ..	1000
aromatic; Products of action of formaldehyde and bisulphites on — and on their derivatives. Lepetit	566	Fixation of — in soils. McBeth	728
Catalytic decomposition of —. Sabatier and Gaudion	1012	formation in soil; Effect of different salts on —. Koch	1057
fatty; Limited action of — on phenazthionium salts. Kehrman	209	generator. (P) Vogt	83
Formation of nitriles from — with the same number of carbon atoms. Sabatier and Gaudion	979	Haber process for synthesis of —. Parsons	1081
Reduction of aromatic nitro-compounds to —. (P) Badische Anilin und Soda Fabr.	1042r	industry; By-product — in United States. Parsons	1082
Researches on —. Shepard	26	leaching of Calumet copper ore tailings. Benedict ..	966
Separation of secondary arylamines from primary —. Thomas	865	liquor; Recovery of — from producer or other gas. (P) Moore	332r
Transformation of secondary and tertiary — into nitriles. Mailhe and De Godon	1193	Manufacture of —; (P) Badische Anilin und Soda Fabr.	1235r, 1272r
Amino-acid nitrogen; Determination of — in blood. Bock	231	(P) Classen	547
Amino-acids; Esters of <i>p</i> -benzarsinic acid with —. Sieburg	1027	(P) Devaueille and Bensa	1093
Influence of — in the estimation of raffinose and sucrose in molasses by the inversion method. Stanek	931	(P) Ellis	32
from proteins; Improvements in the copper method for determining —. Kober	664	(P) Perry	215
Separating glutamic acid from other —. (P) Corti ..	979	Manufacture of carbonic acid compounds of —. (P) Badische Anilin u. Soda Fabr.	215r
Aminoalkyl esters; Relation between chemical constitution and physiological action in certain substituted —. Pym	472	Manufacture of — from coke. (P) Aarts	136
1-Aminoanthraquinone; Manufacture of an insoluble azo dyestuff from —. (P) Badische Anilin und Soda Fabr.	78	Manufacture of nitrile acid from —; (P) Ellis, and Ellis-Foster Co.	1007
2-Aminoanthraquinone and its derivatives; Manufacture of —. (P) Bayer and Co.	512	Parsons	1083
4-Amino-2-auromeraptobenzene-1-carboxylic acid; Sodium salt of —. (P) Meister, Lucius, u. Brüning	163	Manufacture of nitrogen oxides from — (P) Busvold	646
Aminobenzophenone; Action of alcoholic caustic potash on halogenated —. Montagne	207	Manufacture of — from sodium cyanide. Bucher ..	452
Aminobenzyl alcohols; Tertiary — and their derivatives. Von Braun	286	Micro-titration of —. Barnett	615
Amino-derivatives of complex aromatic hydrocarbons; Additive compounds of <i>s</i> -trinitrobenzene with —. Cadre and Sudborough	128	from nitrogen in brewing materials; Determination of — by the boric acid method. Adler	157
Aminohydroxy compounds; Electrolytic manufacture of aromatic —. (P) Soc. Chem. Ind. in Basle 129, 1126r		obtained as by-product of low-temperature carbonising. Maclaurin	625
<i>p</i> -Amino- <i>p</i> -methylhydridene and its <i>p</i> -hydroxy derivative; Comparative physiological properties of —. Von Braun and Danziger	612	in opium. Rakshit	472
from <i>o</i> -xylylene cyanide. Von Braun and others	234	oxidation; Chemical control of —. Fox	1005
2,5,7-Aminophenol-sulphonic acid; Manufacture of acyl derivatives of —. (P) Chem. Fabr. Griesheim-Elektron	542	Oxidation of — to nitric acid. Maxted	777
Amino-nitrogen; Gasometric determination of — in worts, extracts, etc. Einslander	399	oxidation process. (P) Ellis	1094
<i>p</i> -Aminophenol; Electrolytic manufacture of —. (P) Soc. Chem. Ind. in Basle	120	Oxidising — and catalytic bodies therefor. (P) Parsons	1127
<i>p</i> -Aminophenylarsinic acid; Preparation of thionrea compounds of — or of its homologues and derivatives. (P) Thoms	403	Presence of — in diseased plants. Relationship of oxidases and diastases to the disturbance. Bonequet	1142
		Presence of — in diseased plants; Its significance with regard to crop rotation and soil depletion. Bonequet ..	41
		process; Work of the Nitrogen Products Committee on the synthetic —. (P) Giddens	1198
		Purification of —. (P) Giddens	646
		recovery from coal gas, and intensive scrubbing. Blaauvelt	125
		Role of — in the metabolism of nitrogenous substances in plants. Praichnikov	898
		in soils; Effect of paraffin on accumulation of —. Gaihey	1141
		Synthesis of —; Le Châtelier	545
		Maxted	777
		Use of nitre cake in the manufacture of pure —. Terlinek	1216a
		Use of nitrogen oxides from — in the lead chamber sulphuric acid process. Petersen	641
		Vapour pressure at low temperatures, and boiling point of —. Burrell and Robertson	711

	PAGE		PAGE
Ammoniacal liquor; Extracting ammonia from — (P) Schuster, and British Coke Ovens, Ltd.	1272r	Amylaceous materials; Digesters for boiling — under pressure. (P) Boulard	1189
liquor; Extraction of cyanides from — (P) Baker	1272	substances; Liquefying and saccharifying — (P) Boidin and Eiffront	732r
liquor; Improving the fertilising value of — (P) Schubert	299, 607r	Amylase, malt-; Effect of bromides on action of — Thomas	974
Ammonification in soils; Nature of — Miyake	227, 1281	malt-; Influence of certain electrolytes upon the course of hydrolysis of starch by — Sherman and Walker	971
Ammonite as a permitted explosive	1151	of malt; Modification of amylolytic activities of — and their behaviour on keeping in presence of different reagents. Chrząszcz and Joscht	901
Ammonium chloride; Stability of — Gelhaar	101	in potato tubers; Part played by the — Bolnár and Doby	98
chloride and formaldehyde; Mechanism of the interaction of — Werner	1147	Amylene, <i>β</i> -iso-; Action of anhydrous aluminium chloride on — Gangloff and Henderson	956
chloride; Manufacture of — (P) Precht	548	Anæsthetic drugs; Tests for certain — Haukin	565
chloride; Manufacture of — direct from chlorine, nitrogen, and hydrogen. (P) Mayer	137	Anæsthetics; Effect of — on cyanogenetic compounds of <i>Sorghum vulgare</i> . Williamson	400
chloride; Manufacture of fertilisers containing ammonium magnesium sulphate and — (P) Precht	398	Anajá oil. See under Oils, Fatty.	
chloride; Recovery of — in manufacture of gas or coke. (P) Myers, and Shelton Iron, Steel, and Coal Co.	497	Analysis, electro-; Apparatus for — Jones	1195
chloride; Utilisation of — as food by bakers' yeast. Hoffman	350	Electrolytic — with small platinum electrodes. Gooch and Kobayashi	671
fluorides; Manufacture of — (P) Chappell, and Mineral Products Corporation	1047	gravimetric; Contamination of precipitates in — Solid solution and adsorption <i>versus</i> higher order compounds. Smith	907
magnesium sulphate; Manufacture of fertilisers containing ammonium chloride and — (P) Precht	398	Use of Methylene Blue as a reagent in chemical — Application to the detection and determination of perchlorates in Chile saltpetre. Monnier	49
molybdate; Recovery of — from filtrates obtained in estimation of phosphoric acid. Kinder	945	Analytical chemistry; Suggested central school of — Menzies	993
molybdate solutions; Yellow deposit found in — Penfold	384	Andiroba oil. See under Oils, Fatty.	
nitrate; Manufacture of — (P) Ilulin	137	<i>Andropogon sorghum</i> seeds; Kafirin, an alcohol-soluble protein from — Johas and Brewster	153
(P) Norsk Hydro-Elektrisk Kvaelfabrikationselskab	1007	Aniline; Catalytic formation of — from substituted anilines. Sabatier and Gaudion	1042
nitrate and other products; Manufacture of — (P) Washburn	503	Colorimetric determination of small amounts of — Elvove	1231
nitrate; Purification of — by "clairage" or by fractional crystallisation. Rengade	961	Formation of — from ammonia and benzene at high temperatures and in presence of contact substances. Wibaut	638
nitrate and sodium bicarbonate; Manufacture of — (P) Ricard	137	Hypochlorite colour reaction of — Shepard	27
nitrate solutions; Tables for the preparation of — of any desired strength. Gautsch	135	Utilisation of hypochlorite colour reactions in establishing the mechanism of action of dimethyl sulphate on — Shepard	26
phosphate, acid; Manufacture of — (P) Wollenweber	138r	Animal by-products; Disinfection of — for importation into United States	39
phosphomolybdate precipitate; Occlusion of iron by the — Archibald and Keegan	355	dips; Chemical composition of lime-sulphur — Chapin	232
polythionate and ammonia; Reactions between — Espenhahn	484	washes. (P) Lemmens and Fryer	611, 1247r
polythionate, sulphur dioxide, ammonia, and ammonium sulphide; Reactions between — at 100° C. Espenhahn	487	Animals, aquatic; Production of a nutritious extract from — (P) Coons and Hewitt	232
polythionate, sulphur dioxide, and ammonia; Reactions between — at 100° C. Espenhahn	486	Annealing of arsenical brass. Smalley	438
polythionate-thiosulphate solutions. Espenhahn	483	articles; Method of — (P) Pollard	655
salts; Characteristic effect of — on plant physiology. Söderbaum	467	furnaces: (P) Grocott	1240
salts; Exportation of — Morosov	898	(P) Smallwood	36
salts; Function of calcium in the nutrition of garden pea seedlings with — Moir	571	(P) Smallwood, and American Incandescent Heat Co.	699
salts; Rapid method of analysing — Moir	571	(P) Stevens	537
silicate. Schwarz	135	furnaces; Doors of gas-heated — (P) Dowson and Mason Gas Plant Co., and others	1135
soaps of colophony. Paul	557	furnaces; Gas-heated — (P) Dowson and Mason Gas Plant Co., and others	1100
sulphate; Appointment of committee on supply of — Comparative action of — and of sodium nitrate and some organic nitrogenous manures. Jakouchkine	213	furnaces heated by gaseous fuel. (P) Allways and Onions Pneumatic Engineering Co., and Allways	329
sulphate; Comparison of — with calcium cyanamide for manuring sugar cane. Goerts	1058	leers. (P) Plante	537
sulphate; Direct process for manufacturing — Cook	997	by means of gas. Walter	340
sulphate; Effect of — on soil acidity. Allison and Cook	972	of metal articles; Preventing scaling in the — (P) Perry, and Metalloids, Ltd.	769
sulphate; Effect of soil reaction on the availability of — Cook and Allison	932	of metals; Clean — Scott	143
sulphate; Manufacture of — (P) Adam	1007	metals; Furnace for — (P) Masters	1182r
(P) Ritter-Conley Manufacturing Co., and Carpenter	548	ovens. (P) Duckham	1013
sulphate; Manufacture of neutral — (P) Capron	1093	Annual meeting; Proceedings of the thirty-sixth — at Birmingham	741
sulphate and muriate works; Report on — by the Alkali Inspector	991, 992	Anole slimes from copper refining; Treatment of — Johnson	805
sulphate; Oxidation of ammonium sulphite to — (P) Elektrizitätswerk Louza	1093	Anodes for electroplating. (P) Jones	222
sulphate; Possible partial substitution of nitre-cake for sulphuric acid in the manufacture of — Parrish	336	Anthracene; Solubility of — in various solvents. Hildebrand and others	1267
sulphate prices	619	Anthracene dyestuffs: Alizarin; Production of fast dyeings with — Döhl	501
sulphate and sodium nitrate; Comparison between effects of manuring potatoes with — Zasukhin	95	Indanthrene; Manufacture of a chlorine derivative of — (P) Chem. Fabr. Griesheim-Elektron	591
sulphate solutions; Action of — on muscovite. Gardiner and Shorey	896	Indanthrene; Manufacture of polychloro substitution products of — (P) Meister, Lucius, u. Brüning	591
sulphide, ammonium polythionate, sulphur dioxide, and ammonia; Reactions between — at 100° C. Espenhahn	487	Indanthrene series; Production of finely divided pigment dyestuffs of the — (P) Meister, Lucius, u. Brüning	78
sulphite; Oxidation of — to ammonium sulphate. (P) Elektrizitätswerk Louza	1093	Manufacture of — (P) Badische Anilin und Soda Fabr. .. 78r, 78r, 131	1174
thiocyanate and formaldehyde; Condensation product of — Schmöder	942	Manufacture of green vat — (P) Badische Anilin u. Soda Fabr.	382r
thiosulphate-polythionate solutions. Espenhahn	483	Manufacture of vat — (P) Wedekind and Co.	639
thiosulphate and sulphur dioxide; Reactions between — Espenhahn	483	Manufacture of yellowish-brown vat — (P) Badische Anilin u. Soda Fabr.	382r
Ammunition; Investigation of defective small-arms — at Washington, U.S.A.	1195	Turkey-red; Production of fast dyeings similar to — (P) Meister, Lucius, u. Brüning	81
Amygdalin; Constitution of — Bau	905		
Amyl compounds; Purification of — (P) Essex and others	1029		

	PAGE		PAGE
Anthraquinone: Action of acetaldehyde-ammonia on —, Ghosh	958	Argentine, Quebracho extract manufacture in —	226
compounds: (P) Badische Anilin und Soda Fabrik	1031r	Argillaceous compositions; Manufacture of —, (P) Minton and Herbst	839
derivatives: Reduction of — in concentrated sulphuric acid solution by means of aluminium powder, Eckert and Pollak	866	Arginine; Ascorbate determination of — in proteins, Jensen	562, 661
group; Arsenic compounds of —, Benda	1247	Argon; Apparatus and process for concentrating —, (P) Fonda, and General Electric Co.	215
series; Manufacture of combustion products of the —, (P) Durand et Huguenin S.A.	1171	Electric incandescent lamps filled with —, (P) Allgem. Elektrizitäts-Ges.	1000
Solubility of — in various solvents, Hillebrand and others	1267	and nitrogen; Apparatus for determination of —, (P) Brandt	616
Anthraquinone-1-diazonium halides, Schaarschmidt	209	Armour and Co.; Activated sludge sewage purification plant of — at Chicago, Ardern	827
Anthrax serum; Immunity studies on —, Eichhorn and others	392	Army stable manure; Composition of —, Russell	337
Antidiphtheritic serum; Selective adsorption of — by aluminium hydroxide, Rakuzin and Flier	735	Aromatic compounds; Action of aromatic alcohols on — in presence of aluminium chloride, Huston and Friedmann	26
Antimonides; Production of —, (P) Eyer, and Koeppe and Co.	215r	compounds; Production of — from petroleum oils, (P) Mann and others	332
Antimonial lead; Analysis of —, McCabe	141	series; Condensations in the — by means of heat, Meyer and Holmann	865
Antimony; Colloidal — with <i>Tubera salep</i> extract as protective colloid, Gauthier and Kräutle	913	Arsinic acid. See <i>p</i> -Aminophenylarsinic acid.	
Determination of — in white metal alloys, Howden	1276	Arsenates; Manufacture of metallic —, (P) Marks and Mitchell	339r, 503r
Electro-deposition of — from fluoride baths containing addition agents, Mathers and others	1099	Toxic values of —, Lovett and Robinson	1061
Electrolytic production of — direct from stibnite ore, Demarest	1180	Arsenic; Application of Gutzeit test to works' determination of —, Hollins	576
ores; Occurrence and utilisation of —, 87		Colloidal — with <i>Tubera salep</i> extract as protective colloid, Gauthier and Kräutle	913
plating baths; Tests of —, Mathers and others	1099	Destroying organic matter preparatory to detection of —, Gauthier and Claumann	908
Recovery of — from its ores by volatilisation processes, De Cew	551	Determination of — in glucose, Kling	1283
tin, lead, and copper; Analysis of alloys of —, Hagmann	221	Determination of — in organic compounds, Ewins	166
and tin; Separation of — by hydrogen sulphide in hydrochloric acid solution, Prim	737	Determination of small quantities of —, Klason	474
Antimony compounds as opacifiers in enamels, Staley	879	Determination of — in water, Winkler	665
-mercury compounds of dihydroxydiamino-arsenobenzene, (P) Danyasz	906	Influence of — in brass, Smalley	429
-silver, etc., compounds of dihydroxydiamino-arsenobenzene, (P) Danyasz	907	in lead arsenate; Boiling method for determination of water-soluble —, Gray and Christie	41
sulphide and cuprous sulphide; Metallographic examination of the system —, Chikashige and Yamuchi	142	in lead arsenite; Rapid determination of water-soluble —, Scholz and Wabstein	977
sulphide; Manufacture of golden — in France	492	Manufacture of pharmaceutical products containing —, (P) Callson and others	162
Antiparasitic composition for plants, (P) Vecelli	233r	Preparation of pure zinc for detection of —, Lemkes	475
Antipyretics; Manufacture of —, (P) Burr	1061	Separation of germanium from —, Browning and Scott	1196
Antipyrine; Determination of —, Bougault	667	in sulphuric acid; Critical examination of Lange's method for rapid determination of —, Pérégryn	335
François	353	works; Report on — by the Alkali Inspector	991
Antiseptic action of tar oils; Improving the —, (P) Noerdlinger	15r	Arsenic compounds; Activation of therapeutic action of quinine and mercury by organo-metallic —, Gautier	568
materials, (P) Billing	161	compounds of anthraquinone group, Benda	1247
A new —, mercuriophen, Schamberg and others	733	compounds; Esters of aromatic — and amino-acids and higher alcohols, Sieburg	1027
power and valency; Relationship between —, Friedberger and Juchaczmagin	665	trisulphide, Schmidt	925
properties of nitrous air, Colin	977	Arsenobenzene derivatives containing nitrogen; Preparation of —, (P) Meister, Lucius, u. Brüning	403
properties of starch iodide, Lamière	1061	Arseno-compounds; Manufacture of complex —, (P) Meister, Lucius, and Brüning	353r
Antisepsis; Comparative study of various — for preventing infection of wounds, Vincent	471	Arsenophosphorus compounds; Manufacture of organic —, (P) Monneyrat	943
Effect of glycerin on —, Goodrich	610	Arylalkylhydantoin; Manufacture of —, (P) Meister, Lucius, u. Brüning	615
New and powerful —, Flavine and Brilliant Green, Browning and others	161	Arylamides of 2-hydroxynaphthalene-3-carboxylic acid; Preparation of —, (P) Meister, Lucius, and Brüning	286
Regular and irregular —, Riehel and Cardot	1246	Arylamines; Separation of secondary — from primary amines, Thomas	865
Riehel and others	610	Asbestos and cement; Manufacture of artificial slates from —, (P) Imer-Schneider	219
Similarity between lactic organisms and streptococci from point of view of action of —, Cardot	1026	Drying apparatus for —, (P) Bourque	583
Antitoxic sera; Influence of the reaction of — in their concentration, Homer	731	Industry of Cape Colony, Frood	82
Antitoxin, hog-cholera; Treatment of —, (P) Riehel and others	663	phthalised; Analysis of —, Ivanov	290
Antitoxins; Adsorption of — by aluminium hydroxide, Rakuzin and Flier	305	preparation, Klingert, Dubosc	23
Aouara palm oil. See under Oils, Fatty.		Ascension pipes of by-product ovens, furnaces, and the like, (P) Proctor	922r
Apatite; Neodymium as the cause of the red-violet colour in certain specimens of —, Wherry	455	<i>Asclepias frutescens</i> fibre and floss from S. Africa	1003
Apple juice; Proportion of levulose in —, Eoff	993	<i>Aspergillus niger</i> ; Citric acid fermentation of —, Currie	975
Applied chemistry; Reports of progress of — 3, 103, 167, 241, 309, 357, 497		Formation of starch-like substances by —, Boas	1024
Apyrene. See Lithium acetylacrylate.		<i>Aspergillus oryzae</i> ; Tannase of —, Kita	901
Aquatic animals; Production of a nutritious extract from —, (P) Coons and Hewitt	232	Asphalt emulsions and the like, (P) Wood	1231
Aqueous-alcoholic solutions; Calculation of specific heats of —, Kolobovskii	307	cement; Manufacture of — from natural asphalt, (P) Barber Asphalt Paving Co.	34r
Arabinose; Kinetics of furfural formation from —, Krennau and Klein	899	Effect of sulphur on oxidation of hydrocarbons with particular reference to —, Brooks and Humphrey	997
<i>l</i> -Arabinose; Oxidation of — in alkaline solutions with air and with cupric hydroxide, Nef and others	1022	-like masses and derivatives; Manufacture of —, (P) Landsberg	206r
<i>p</i> -Tolylhydrazine of —, Van der Haar	662	limestone; Production of synthetic —, (P) Zimmer	1095
Arachin; Distribution of the basic nitrogen in —, Johns and Jones	732	natural; Manufacture of asphalt cement from —, (P) Barber Asphalt Paving Co.	33r
a globulin from the peanut (<i>Arachis hypogaea</i>) Johns and Jones	458	Nature and origin of —, Richardson	204
<i>Arachis hypogaea</i> ; Proteins of —, Johns and Jones	158	Specific heat of —, Kuno-shita	597
Arachis nuts; Manufacture of food compositions from —, (P) Fleming	351	Asphaltic material; Production of a plastic —, (P) Baskerville	922
nuts and pea beans; Milk substitute made from —, (P) Melnisch	1287r	Asphalts; Relations of effect of overheating to certain physical and chemical properties of —, Hixon and Hands	920
oil. See under Oils, Fatty.

zinc industry	311
Auxinones; Some effects of — on the growth of <i>Lemna minor</i> in mineral culture solutions. Bottomley	723
Some effects of — on soil organisms concerned in the nitrogen cycle. Mockeridge	729
Avocado; <i>d</i> -Mannoketoseptose, a new sugar from the —. La Forge	223
Azides; New —. Wöhler and Martin	669
Sensitiveness of — to detonation. Wöhler and Martin	570
Azine dyestuffs; Notes on —. Kehrman	639
Azo dyestuffs; Effect of additional auxochromes on colour of —. Ghosh and Watson	1126
Manufacture of —:	
(P) Chem. Fabr. Griesheim-Elektron	78
(P) Fiechslender and others	342
(P) Frank	542
Manufacture of acid mono- — for wool. (P) Bayer and Co.	591
Manufacture of blue tetrakis- —. (P) Act.-Ges. f. Anilinfabr.	1171
Manufacture of chromium compounds of —. (P) Soc. Chem. Ind. in Basle	542, 542r, 1231r
Manufacture of copper compounds of <i>o</i> -hydroxy- —. (P) Soc. Chem. Ind. in Basle 382, 382r, 382r, 959r, 1092r, 1092r	
Manufacture of direct cotton —. (P) Soc. Chem. Ind. in Basle	210
Manufacture of direct <i>o</i> -hydroxy- —. (P) Soc. Chem. Ind. in Basle	210, 211r
Manufacture of dis- —:	
(P) Act.-Ges. f. Anilinfabr.	331r
(P) Schülle	1126
Manufacture of green chromium compounds of —. (P) Soc. Chem. Ind. in Basle	331r
Manufacture of <i>o</i> -hydroxyazo- —, and their application in dyeing. (P) Soc. of Chem. Ind. in Basle	78
Manufacture of <i>o</i> -hydroxyazo- —. (P) Act.-Ges. f. Anilinfabr.	110r
Manufacture of insoluble —. (P) Badische Anilin und Soda Fabr.	649
Manufacture of insoluble — from L-aminonaphthoquinone. (P) Badische Anilin und Soda Fabr.	78
Manufacture of leucotriarylmethane — and of their copper compounds. (P) Soc. of Chem. Ind. in Basle	1002
Manufacture of leucotriarylmethane — and their metal compounds and their application in dyeing. (P) Soc. Chem. Ind. in Basle	500
Manufacture of — and of their metal compounds, and their application in dyeing. (P) Soc. Chem. Ind. in Basle	1174
Manufacture of metal compounds of <i>o</i> -hydroxy- — and their application in dyeing. (P) Soc. of Chem. Ind. in Basle	73, 78, 332r
Manufacture of mono- —. (P) Mensching and Mounsey	383r
Manufacture of mono- — suitable for the preparation of pigments. (P) Badische Anilin u. Soda Fabr. 592, 639	
Manufacture of orange red — able to be chromated. (P) Soc. of Chem. Ind. in Basle	131r

Azo dyestuffs—cont.

Manufacture of secondary <i>o</i> -hydroxydis- — capable of being chromed —. (P) Fabr. Prod. Chim. ci-dev. Sandoz	27r
Manufacture of tris- —:	
(P) Act.-Ges. f. Anilinfabr.	211
(P) Ehrhardt	1043
(P) Stebbins	1043
Manufacture of wool dis- —. (P) Soc. of Chem. Ind. in Basle	1092
Methyl red as an indicator. Lehmann and Wöhl	941
Palatine Chrome Black 6 B; Preparation of —. Tomioka	1043
Production of dyes fast to washing, with —. (P) Bayer and Co.	213
Production of — on the fibre. (P) Bayer and Co.	81, 594
Production of — from nitrosamine colours in multi-colour printing. (P) Chem. Fabr. Griesheim-Elektron	344
from <i>o</i> -styrylbenzimidazoles. Kym and Jurkowski ..	209

B

Babassu oil. See under Oils, Fatty.

Babbitt metal; Analysis of —:	
Hagmner	221
Witt	554
Babul pods as tanning material in India	559
Bacilli; Pure-culture apparatus for —. (P) Magat	394
Search for typhoid and paratyphoid — in feces and water. Dienert and Mathieu	232
<i>Bac. coli</i> ; Enumeration of — in potable waters. Bourdet	99
<i>Bac. invertenti aceti</i> . Mezzadrol	1024
<i>Bac. invertenti lactici</i> . Mezzadrol	1024
<i>Bac. lactis acidi</i> ; Alterations in the amount of enzymes in —. Euler and Griese	1283
<i>Bacillus paratyphicus</i> . Ducháček	1189
Bacteria; Action of — in the tissues of plants. Berthold	1058
of alfalfa; Effect of phosphorus on —. Truesdell ..	606
of the coli-aerogenes family; Chemical methods for differentiating —. Clark and Laubs	939
of the coli-typhosis group; Conversion of histidine into ureoacetic acid by —. Raistrick	731
Decomposition of proteins by the action of —. Robinson and Tartar	732
extremator. (P) Kleckner	734
Manufacture of a leather substitute from tanned films of —. (P) Siebold	895
Manufacture of manure by means of —. (P) Thompson	229
A new type of chemical change produced by —. Raistrick	731
Nitrogen-fixing power of soil — that develop on dextrose-agar. Emerson	932
nitrogen-fixing; Russian studies on —. Omelianskij and Solunskov	40
Non-spore-forming — in soil. Conn	971
Production of phenol by —. Berthelot	469
soil; Effect of acids and alkalis on — in the soil solution. Gruzit	605
Spore-forming — in soil. Conn	971
sucrose-inverting; Use of — for manufacture of lactic acid, acetic acid, and acetone. Mezzadrol	1024
Use of manganese as catalyst in atmospheric nitrogen fixation by plants through agency of —. De Gregorio	299
in water; Direct microscopical counting of —. Nelson	470
Bacterial activities of soils; Influence of salts on —. Greaves	227
Bacteriological examination of water; Culture media employed in —. Neutral red-lactose-peptone media. Chaimot and Sherwood	1026
Bacteriology of silage. Sherman	1144
<i>Bact. phenologenes</i> , a new species of bacteria producing phenol. Berthelot	469
Baked articles; Determination of sugar in —	856
Baking powders:	
(P) Royal Baking Powder Co.	470r
(P) Vaygonny, and Royal Baking Powder Co.	401
Balinese sheet of the Society, Dec. 31, 1916	618
Ball-mills. (P) Everett and Co., and Everett	584
Ore-pulverising —. (P) Eggers	1015
Banana stalks as a source of potash. Billings and Caristic ..	349
Bananes; Production of dyes or stains from —. (P) Coe and Coe, jun.	923
Bandrowski's base. See Tetra-amino-diphenyl <i>p</i> -azo-phenylene.	
Barbituric acid derivatives; Manufacture of compounds of alkyls of the morphine group with —. (P) Soc. of Chem. Ind. in Basle	979
Preparation of ether-like derivatives of —. (P) Bayer and Co.	306

	PAGE		PAGE
Barbituric acids; Substituted — (P) Ifiemenz and others	473r	Beers; Study of American —. Tulman and Riley	900
Barium and zinc; Separation of — from ores. (P) Wright and others	110	See also Albs.	
Barium aluminate; Manufacture of —. (P) Hershman, and Armour Fertilizer Works	1128	Beetroot affected with "curly leaf"; Presence of nitrites and ammonia in —. Relation of oxidases and diastases to the disturbance. Bonequet	1142
aluminate; Manufacture of — and of sulphur. (P) Hershman, and Armour Fertilizer Works	1128	Effect of addition of sulphuric acid to soil on growth of molasses; Its composition and utilisation. Osborn	1187
carbonate; Temperature of formation and decomposition of — under a pressure of one atmosphere. Hedvall	643	molasses; Influence of raffinose in — on determination of sucrose by double acid polarisation or by inversion with invertase. Pellet	935
chloride; Removal of — from brines used in the manufacture of salt. Skinner and Baughman	131	molasses; Pentose content of —. Pellet	935
chloride-sulphuric acid; Electrolysis of the system —. Müller	146	Process of treating sugar —. (P) Benjamin	155
compounds in glasses. Williams and Cox	712	Squonin in extracted —. Andrik	560
fluoride; Use of — for prevention of "dryer scum" on bricks. Staley	877	seeds; Ground sugar — as fodder. Kling	1060
hydrogen oxalates. Bruhns	1175	sugar factories; Frothy fermentation of second jet massecuites and after-products in —. Gillet	899
oxide; Manufacture of —. (P) Kremers	1235	Zymase and carboxylase in the storage organs of sugar —. Bodnar	97
oxide; Reactivity of silica with — in the solid state. Hedvall	643	Balt fellowship for scientific research	51
peroxide as substitute for nitre in glass batches. Springer	873	Belts; Impregnating woven —. (P) Andersen	451r
sulphate; Effect of adsorption on physical character of precipitated —. Weiser	644	Process for treating textile fabrics for the manufacture of —. (P) Aktieselskabet Drivremmefabriken "Dana"	80
sulphate; Properties of —. Karaoglanow	736	Treating fabric for power transmission —. (P) Barrell	450
Bark extracts; Process for obtaining —. (P) Reynolds	559	Benzaldehyde; Action of anhydrous aluminium chloride on —. Gangloff and Henderson	956
Barley; Behaviour of mineral substances of — during germination. Windisch and Dietrich	608	Determination of chlorine in synthetic —. Salamon	352
Evidence of existence in malt of an enzyme hydrolysing the furinoids of —. Baker and Hulton	398	Benzanthrone and its derivatives; Synthesis of —. Schaarschmidt	591
extract; Determination of —. Kutscha	515	p-Benzarsine oxide. Sieburg	1027
Making power of various sorts of —. Schjering and Hempel	978	p-Benzarsinic acid; Esters of — with amino-acids and higher alcohols. Sieburg	1027
Proteins of — in the grain itself and during the brewing processes. Schjering and Hempel	973	Benzene; Action of ammonia and calcium on —. Dumaniski and Zvereva	287
restriction order —. Sieburg	479	and ammonia; Formation of aniline from — at high temperatures and in presence of contact substances. Wibaut	638
seedlings; Effect of concentration of hydrogen and hydroxyl ions upon the growth of —. Hoagland	973	Analysis of light oils for xylene, toluene, and —. Egloff derivatives; Toxicity of various — to insects. Moore	939
Utilisation of nutrient value of — in brewing. Busemann	399	Determination of — in coal tar oils. Barker	590
Base-exchanging bodies; Manufacture of —. (P) Rudorf	1047	Determination of — in crude benzols. Spielmann and Petrie	832
-exchanging silicates; Manufacture of —. (P) Kriegshelm, and Permutit Co.	215, 503r	Electrochemical chlorination of —. Fichter and Glantzstein	207
substances; Regenerating —. (P) Staten Island Chemical Corporation, and Foster	977	Oil washing for recovery of — from coal-gas. Adam	331
Bases, phenolic; Researches on —. Von Braun and Danziger	612	from petroleum. Bender	582
Basic brick. (P) Kennedy	1131	Proposed manufacture of — in Australia	705
refractories used in smelting operations; Effects of furnace conditions on —. Wasum	1274	Sources of — for high explosives. Rhead	764
Basal wood; Composition of —. Schorger	867	Thermal decomposition of —. Zanetti and Egloff	499
See also Benzol.			
Batava oil. See under Oils, Fatty.			
Bates, artificial; Stabilising —. (P) Riebenschalm	605	Benzenedisulphonic acid; Separating — from sulphuric acid, and converting it into a salt. (P) Denais	705
Batik work; Method of producing special effects in —. (P) Diener	213	Benzenemonosulphonic acid; Preparation of —. (P) Comp. Prod. Chim. d'Alais et de la Camargue	705
Biting skins. (P) Meister	151	Benzenesulphonic acid; Separating — from sulphuric acid, and converting it into a salt. (P) Dennis	382
Bauxite for lining furnaces. Lecesse	1094	Benzine; Production of — by heating lignite products under pressure. Fischer and Schneider	587
Recovery of aluminium from —. (P) Weaver Co.	341r	See also Petroleum spirit.	
Bay oil. See under Oils, Essential.			
Beans, jack; Proteins from —. Jones and Johns	158	Benzol in coal gas; Apparatus for determination of —. Copp	378
Bearing; Alloy —. (P) Sandell and Mills	601	In coal gas; Determination of — and still for separating the benzol from the absorbing oil. Duvall	25
metals; Manufacture of —. (P) Kelly	1015	crude; Ministry of Munitions order relating to dealings in —. Spielmann and Petrie	918
metals; Manufacture of white —. (P) Hasler	889	crude; Observations on —. Spielmann and Petrie	831
(P) Maschinenbau-Anstalt Humboldt	889	crude; Obtaining valuable products from waste hydrocarbonaceous residues produced in the rectification of —. (P) Sheard	1208
Beater mills; Rotary —. (P) Sturtevant, and Sturtevant Mill Co.	376, 376, 376	crude; Still for fractional distillation of —. (P) Suller and Co., and Bellerby	590
Beech nut cake as feeding-stuff. Kling	1060	Distillation of — from wash oils, and still therefor. (P) Simon-Carves, Ltd., and Brown	1231
Beechwood creosote; Commercial —. Smith and Acree	448	Extracting — from heavy oils. (P) Barbet et Fils et Cie.	705r
Beef; Changes in fresh — during cold storage above freezing point. Hoagland and others	937	extraction in gas works. Clegg	1220
Beer, bottled; Iron content of brewing materials in relation to sedimentation in —. Fischer	901	Gas washing for —; analysis of products; control of stills. Edwards	539
Brewing of —. (P) Floto	97	New method of extracting — from coal gas. Lessing	103
Compounds for preserving —. (P) Rottenkolber	516	plant residues; Recovery of resins from —. (P) Darrin, and Koppers Co.	1012
Concentration of hydrogen ions in — and in the course of its manufacture. Einslander	156	Production of — from heavy oils. (P) Anderson and Meikle	1001
Distribution of nitrogen in —. Sharpe	1059	recovery from coal gas by a modified dehydrating plant. Keable	586
Low-alcoholic —. Overbeck	300	recovery from coal-gas; Physico-chemical considerations on —. Rhead	331
Manufacture of dry extracts of —. (P) Heuser	903	recovery after the war. Sperr	284
Oil in adjuncts and its effect on quality of —. Dreesbach	1106	recovery from gas. Wilson	24
Pasteurising apparatus for —. (P) Lindgren	469r	recovery in gas works. Bugley	21
Pre-mashine and protein-haze in —. Einslander	156	recovery plant; An experience in a —. Drew	587
Preparation of thin — and substitutes during the war. Windisch	1188	rectification of —. Rhead	381
Process of treating —. (P) Ash, and Gould and Ash	1059	refining; Purification of waste effluents from —. (P) Sheard	565
Sterilisation of —. Peitl	1284	Utilisation of Italian products in preparation of —. Rodano	1091
Sterilisation of — by filtration. Zahn	156	See also Benzene.	
wort; Apparatus for cooling and rousing, and precipitating sludge from —. (P) Nathan	1059		
worts; Gasometric determination of amino-nitrogen in —. Einslander	399		
worts; Manufacture of —. (P) Wahl-Henius Research Laboratory, and Wahl	936		
yoghurt; Production of —. (P) Henneberg	903r

Benzophenone; Basic derivatives of —. Von Braun ..	286
Products of action of heat on —. Meyer and Hofmann ..	865
Benzophenonesulphone series; Studies in the —. Ullmann and Von Glueck ..	209
Benzoquinone; Action of acetaldehyde-ammonia on —. Ghosh ..	958
Benzoyl chloride; Catalytic decomposition of —. Mailhe and De Godon ..	129
Benzoyl derivatives of β -hydroxy- or $\alpha\beta$ -di- or polyhydroxy-antraquinones; Preparation of —. (P) Wedekind and Co.	638
Benzoyl peroxide; Vulcanisation of rubber with —. Stevens ..	108
Benzyl chloride; Manufacture of —. (P) Conant	1002
Beryllium; Alloys of — with aluminium, copper, silver, and iron. Oesterheld ..	342
Melting point and heat of fusion of —. Oesterheld ..	342
Bessemer practice; Temperature measurements in —. Burgess	505
Betaine; Manufacture of — from molasses. (P) Act.-Ges. f. Anilinfabr.	473r
<i>Betula lutea</i> ; Composition of wood of —. Schorger ..	867
Beverage extracts; Manufacture of —. (P) Kellogg	1107r
Beverages containing maltose and/or glucose; Rate of turbidity in —. Homberger and Marvel	231
Extract for carbonated —. (P) Stein and Dehls	1143
hopped; Immersion refractometer in determination of small amounts of alcohol in —. Poyzo	515
malt-; Manufacture of unfermented —. (P) Steine-mann	1143
Manufacture of —:	
(P) Ashus	732
(P) Wallerstein	400
Manufacture of alcoholic —. (P) Deffen	399
Manufacture of carbonated —. (P) Kummerlander ..	516
Manufacture of fermented and distilled —. (P) Wahl-Henius Research Laboratory, and Wahl	936
Manufacture of non-alcoholic —. (P) Straus	608
Manufacture of non-alcoholic, chill-proof —. (P) Beerhalter	1114
Manufacture of non-intoxicating fermented —. (P) Nowak	1285
Manufacture of unfermented —. (P) Heuser	42
Treatment of fermented —. (P) Schmelbe	1144
Bichromates; Chemical evaluation of alkali —. Sacher ..	925
Bihar; Java Indigo in —. Reid	333
Rice from —. Sen	159
Third report on improvement of indigo in —. Howard ..	130
Bile enzymes; Stabilising —. (P) Riebensahn	605
Binder for briquettes from sulphite-pulp waste lyes. (P) Woddrop, and Robeson Process Co.	540
Binding and coating composition. (P) Ellis, and Ellis-Foster Co.	91
composition; Manufacture of plastic —. (P) Vail ..	86
composition for roads, etc. (P) Tompkins, and Binder Co.	341
compound; Manufacture of — from coal tar, etc. (P) Evans and Mitchell ..	129r
material for bricketting iron ores and flue-dust; Pre-paration of a —. (P) Freiherger ..	343
material for iron ore brickettes; Manufacture of —. (P) Mathies	1012
Biochemical phenomena of simultaneous oxidation and reduc-tion. Abelous and Aloy ..	1024
synthesis of a second galactobiose by means of emulgin. Bourquelot and Aubry ..	515
Biochemistry of plants. Stutzer	898
Biological products; Identification and determinatin of lactic acid in —. Phelps and Palmer ..	236
products; Separation and determination of butyric acid in —. Phelps and Palmer ..	567
Birch oil. <i>See under</i> Oils, Essential, yellow; Composition of wood of —. Schorger	867
Birmingham district; Metallurgical industries of the —. Turner	793
Biscuits; Determination of sugar in — ..	856
dog; Volumetric determination of chlorine in — by the wet method without formation of ash. Weitzel ..	1190
Bismuth-tin alloys; Constitution of —. Bucher	652
Bismuth acetate. Salkowski	871
Bisulphite liquor; Apparatus for making —. (P) Stebbins ..	646
Bisulphites and formaldehyde; Products of action of — on aromatic amines and their derivatives. Lepetit ..	566
Bitumens; Effects of exposure on some fluid —. Reeve and Lewis	998
Relations in composition of different forms of natural —. Mabery	1123
Bituminous aggregates; Toughness of —. Reeve and Lewis	1130
cement or composition; Manufacture of —. (P) Illemann	552
cements. (P) Moniva	965
grouting. (P) Lovegrove and Crompton ..	1050r

Blasting cartridges. (P) Weber	48r, 101, 238r, 736r
cartridges in which liquid air is used; Production of —. (P) Kowatsch	473r
charges and cartridges. (P) Weber	1030
explosives. (P) Kynoch Arklow, Ltd., and Pirmez ..	1248
Bleaching; Action of two different processes of — on American cotton yarns. Jecurso ..	288
apparatus; Electrolytic —. (P) Webb and Williams ..	28r
of cellulose; Determination of degree of — by means of the copper value. Freiburger	707
Composition for —. (P) Poulson	1269
detergent, and disinfecting composition. (P) Carmona, and Comp. Exploradora Navezen ..	1045
exotic wool. (P) Simon	139
fabrics in open form; Plant for —. (P) Taylor	1232r
fats, oils, and their derivatives. (P) Reuter, and Reuter Process Co.	463r
and fireproofing fabrics and the like. (P) Craig, and Whipp Bros. and Tod	641r
and ink-removing compound for treating paper stock. (P) Wright	708
kiers; Carriages of —. (P) Jackson and Bro., and Edge	28r
liquids, e.g., sugar juices; Apparatus for —. (P) Foret ..	156
liquors; "Twaddelling" of electrolytic —. Hepburn ..	708
natural and artificial silk, cotton, linen, and other textiles by means of foam. (P) Soc. de Teinture et d'Apprêt Clavel, and Lindenmeyer ..	133, 641r
of oils, fats, and waxes; Catalytic —. Ral	948
process; Conveying cotton, cotton waste, wool, etc., in the —. (P) Taylor and others ..	451
solutions; Electrolytic apparatus for producing —. (P) Holliday and Ward ..	32r
and stoving flannel; Apparatus for —. (P) Woolfenden	212
textile fabrics or like material. (P) Poulson	383
textile fibres. (P) Schaidlauf, and Reussler and Hass-lacher Chemical Co.	1005r
textile fibres or goods; Machines for —. (P) Moysey and Johnson ..	501
Treatment of textile fibres before —. (P) Watremez ..	594
Bleaching-powder; Disinfection of water by means of —. Langer	733
Interaction of — with normal constituents of natural waters and sewage. Helse	1191
Machine for making —. (P) Ishikawa	32
Manufacture of — in chambers or with mechanical apparatus. Schütz	546
Blende. <i>See under</i> Zinc.	
Blood; Adulteration of dried —. Sirot and Joret	933
-clotting substance; Preparation of a lipid-like —. (P) Soc. Chem. Ind. in Basle	1148r
Determination of amino-acid nitrogen in —. Bock ..	231
Preparation of an easily distillable, water-soluble, stable material from —. (P) Sgalitzer ..	665
Preparation of lipid-like nitrogen-containing com-pound from —. (P) Soc. Chem. Ind. in Basle ..	615
Rapid determination of calcium in —. Lyman	561
Board of Fuel Research; Appointment of —	203
of Scientific Societies; Conjoint —	632
Boiler compound. (P) McLeod	202
corrosion; Note on —. McLellan	853
feed water heating apparatus and evaporator; Combined — for power plant. (P) Griseom-Russell Co., and Jones	1227
-feeding means. (P) Emmet, and General Electric Co.	1039
gases; Apparatus for washing and utilising waste —. (P) Sargent and others	995
plates; Embrittling action of sodium hydroxide on mild steel and its possible relation to seam failures of —. Merica	649
tubes; Facilitating transmission of heat by —. (P) Hülsmeier	700
Boilers; Burners for blast-furnace gas, etc., for —. (P) Mackinlay	998
dust-fired; Working of —. King	114
and the like; Preventing fur from depositing in —. (P) Andersen	445
Mercury —. (P) Emmet, and General Electric Co.	1039
steam-; Coal-fired —. (P) Wilkinson	1228

	PAGE
Boiling pans and like apparatus. (P) Senior	1202
points of metals. Johnston	1132
Bone-black; Apparatus for revivifying and decarbonising — (P) Weinrich	700r
Use of vegetable decolorising carbon as compared with — in sugar refining. Weinrich	1106
Books received; Lists of new — 50, 102, 106, 240, 308, 522, 672, 738, 946, 980, 1150	1150
Boots; Utilisation of condemned Army —. Lamb	986
Borax; Extraction of — from mixtures containing boric acid and borax and sodium sulphate. (P) Deutsche Gold- und Silber-Scheideanstalt	1017
Obtaining potassium chloride from certain waters containing —. (P) Wrinkle and Watterson	925
and potassium chloride; Separating mixed —. (P) Pennock and others	456
Recovering — from alkaline deposits. (P) Jones and others	455
Water content of crystallised —. Hoffmann	613
Boric acid; Determination of — in special glasses. Nicolardot and Bondet	713
Boric anhydride and its hydrates. Myers	454
Boron; Case-hardening of iron by —. Tschischewsky	531
Effect of three annual applications of — on wheat. Cook and Wilson	1186
Influence of — on plant growth. Voelcker	95
and iron. Tschischewsky and Herdt	650
-nickel-iron alloys. Tschischewsky and Mikhailovsky	650
-nickel steels. Tschischewsky and Mikhailovsky	650
Preparation of pure —. Podzusz	1012
Production of alloys of — with tungsten, molybdenum, tantalum, etc. (P) Podzusz	929
<i>Boscellia serrata</i> oleoresin in India. Pearson	632
Botany and chemical industry; Prize for essay on inter-connection of economic — 3, 103, 167, 211, 309, 357	1004
<i>Brachystegia Raudii</i> as a paper-making material	1144
Brain in flour and bread; Determination of —. Legendre	608
Brandies; Preparation of —. (P) Disdier	556
Brass borings, turnings, etc.; Separation and extraction of dust and iron from —. (P) Sowden	714
Cartridge —. Brownson	1098
Chromic acid and hydrogen peroxide as etching agent for —. Miller	833
condenser tubes; Corrosion of —. Ramsay	890r
Coverings of crucible furnaces for melting —. (P) Weston	1276
Electric resistance type furnace for melting —. Bailly	110
Failure of —. Merle and Woodward	325
General properties of stampings and chill castings in — of approximately 60/40 composition. Ellis	330
Improving the alloying qualities of manganese with —. (P) Goldschmidt and others	429
Influence of arsenic in —. Smalley	325
Machining properties of —. Ellis	36
melting furnaces. (P) Davis and Twigg	1051
melting furnaces; Fuel economy possibilities in —. Harvey	1182
Melting of or crucible for melting —. (P) Henderson, and Driver Harris Co.	1179
Metallography of —. Development and re-absorption of the α -constituent in alloys normally of the α -type Mathewson and Davidson	599
scrap of high copper content; Re-casting —	143
surfaces; Process of crystallising —. (P) Hasenohr and Debeck	575
Use of nitre-cake as substitute for sulphuric acid in pickling annealed —. Brownson	1097
Brasses; Fatigue of —. Haigh	1180
of Mintz metal type; Corrosion of —. Rawdon	140
of type Cu 60, Zn 40%; Microstructure and initial stress in wrought —. Merle and Woodward	603
Brassicidic, erucic, and isocerucic acids; Isomerism of —. Mascarelli	155
Brazil; Gum-yielding plants of —. Montandon	512
Rubber exports from —	345
Brazilian oil-seeds. Bolton and Bower	301
Brazing material. (P) Fuller and General Electric Co.	1131
steel; Compound for use in —. (P) Buckler	1111
Bread; Determination of bran in —. Legendre	1060
Improvement of war — by neutralising the bran. Lapieque and Legendre	976
and the like; Manufacture of —: (P) Jenkins	302r
(P) Roworth and others	836
-making; Use of brewers' yeast in —. Baker	1114
-making; Use of calcium gluconate in —. Le Roy	608
-making with various flours. Ballard	610
Manufacture of —: (P) Kohnan and others	1288
(P) Wahl, and Wahl Efficiency Institute	903
Manufacture of concentrated —. (P) Heubert	1191
Manufacture of whole-grain —. (P) Gross, and Vollbrodt Patent-Verwertung Ges.	401
Mineral water for use in manufacture of beer. (P) Kohnan and others	401

Brewing. (P) Kenward	976
Apparatus for decarbonating water for —. (P) Werle ..	733
of beer. (P) Floto	97
Economy of fuel which might be effected by prohibition of —. Report of Royal Society Committee ..	198
Eliminating carbonate hardness of water for —. (P) Hess	936
in Germany during the war. Windisch	1188
materials; Determination of ammonia from nitrogen in — by the boric acid method. Adler	157
materials. Iron content of — in relation to sedimentation in bottled beers. Fischer	901
materials; Titration of — in stages by means of two indicators. Reichart	399
Potato starch as malt adjunct in —. Koudelka	399
Pre-mashing and protein-rest in —. Lehmann	515
processes; Proteins of barley during the —. Schjerning and Hempel	973
Saccharification of raw cereal mashes in —. Thevenot ..	900
Utilisation of nutrient value of barley in —. Busemann ..	399
Brick kilns: (P) Heilmann	1049
(P) Kern	86
(P) McArthur and McKergow	926r
(P) Underwood, and Underwood Engineering Co. ..	340
(P) West and Lewis	963
kilns and method of operating them. (P) Vredenburg and Lacey	648
kilns; Treatment of gases from —. Hempel	199
Bricks; Bask —. (P) Kennedy	1131
carbon; Manufacture of —. (P) Chem. Fabr. Albert, and Beroud	85
coke-oven; Physical properties of the two chief mineral constituents of —. Fearnside	216
Discolorations in the manufacture of —. Moore and Mellor	550
Experiments to overcome "scumming" (efflorescence) and improve the colour of —. Williams	877
and the like; Manufacture of —. (P) Tucker and McCool	504
and the like; Properties of —. Proposed German standards. Burkhart	507
magnetite; Spalling of —. Mellor	551
Magnetite — for steel furnaces from the consumer's point of view. Brooke	1274
Paving —. (P) Tucker and McCool	504
Process of burning —. (P) Lambert, and Lambert Process Co.	1130
Refractory —. (P) Youngman	926
refractory; Manufacture of —: (P) Leger	504r
(P) Twynam	86
refractory; Testing of —. Nesbitt and Bell	1048
sand-lime; Manufacture of —. (P) Charlton	1010
sand-lime; Silica bond in —. Emley and others ..	880
Silica —. Le Chatelier	964
silica; Manufacture of —. Nesbitt and Bell	1049
silica — and some new uses for them. Gray	387
silica; Volume changes of mixtures for —. Meltinger and Ross	718
Silica — for steel furnaces from the consumer's point of view. Brooke	1273
Slag paving —. Montgomery and Burdick	719
Specific heat of —. Kinoshita	597
Tunnel dryer for —. (P) Price	1236
Use of barium fluoride for prevention of "dryer seum" on —. Staley	877
Yellow —. Keane	138
Brilliant Green. See under Triphenylmethane dyestuffs.	
Brines; Chemical examination of natural —. Sweeney and Withrow	924
Recovery of salt from its admixture with impurities in crude —. (P) Skinner and Baughman	1271
Removal of barium chloride from —. Skinner and Baughman	134
Briquettes; Binder for — from sulphite-pulp waste liqrs. (P) Woldford, and Robeson Process Co.	510
of coke, turf, iron or other ores or the like; Manufacture of —. (P) Kleinschmidt	76
Compressing fine ores or like substances into —. (P) Klippe	1101

	PAGE
Briquettes— <i>cont.</i>	
Introducing and mixing the binding medium in making (P) Kleinschmidt	447
Manufacture of — (P) Vogel, and General Briquet- ting Co.	379
Manufacture of resistant — (P) Bibb	25r
Presses for production of — (P) Sutcliffe, and Pure Coal Briquettes, Ltd.	205,
of zinc-bearing ore; Manufacture of — (P) Jones	461r
Briquetting coal:	
(P) Hite, and Universal Briquetting Co.	636
(P) Smith	636
fuel; Plant for — (P) Rigby, and Wetcarbonizing, Ltd.	77r
iron ores and flue-dust; Preparation of a binding material for — (P) Freiburger	343
of iron ores; Present knowledge and practice in regard to — Barrett and Rogerson	1095
machine, (P) Lovejoy and Stein	540
metal cuttings, (P) Campbells and Hunter, Ltd., and Korte	557r
of non-ferrous light metal scrap, Stillman	1181
porous materials, as small coke, peat, sawdust, etc., (P) Behr	285
Bristol glazes compounded on eutectic basis; Study of — Watts	716
glazes compounded on norm basis; Study of — Watts	716
glazes; Effect of clay on fusibility of — Hill	716
British chemical industry; Patent law in relation to — Hay	1151
Chemical Manufacturers; Association of —	20
British Columbia; Kelp industry in —	710
British East Africa; Essential oil production in —	1108
Bromates; Detection of — in presence of chlorates and iodates, Monnier	30
Bromatone. <i>See</i> Tribromo-tertiary-butyl alcohol.	
Bromides; Determination of — Rupp	1270
Effect of — on action of malt amylase, Thomas	974
Valuation of — Rupp and Hollatz	924
Bromination of aromatic hydrocarbons by means of bromine and nitric acid, Datta and Chatterjee	26
Bromine contents of German potash salts, original liquors, and eod liquors, Winkler	547
Determination of — in water, Winkler	665
industry at Salin de Giroud, Manzella	641
<i>p</i> -Bromobenzene; Solubility of — in various solvents, Hildebrand and others	1267
Bromocresol, purple. <i>See</i> Dibromo- <i>o</i> -cresolsulphone- phthalein.	
Bromo-derivative of <i>p</i> -aminophenyl salicylate; Manufacture of a — (P) Abelin and Lichtenstein-Rosenblatt	668
Bronze; Chromic acid and hydrogen peroxide as etching agent for — Miller	1098
Improving the alloying qualities of manganese with — (P) Goldschmidt and others	390
Melting — in iron or steel ladles, (P) Cookerley and Shelton	143
New — (P) De Lisle and Héroult	144
powder; Manufacture of — (P) Fuchs	144
Bronzes; Comparative tests on test-bars and actual castings of — Corse and Comstock	1276
Bronzing of metallic surfaces; Electrolytic — (P) Sestini and Rondelli	888
Broom corn for paper pulp, Walsh	1091
Manufacture of a textile fibre from — (P) Zeise-Gött and Sütterlin	869
Brown coal. <i>See</i> under Coal.	
dyeings on fibres; Production of — by oxidation, Diehl	335
Buchu; South African —	1209
Building blocks, slabs, or tiles, (P) Howells	504
materials; Manufacture of —:	
(P) Gürtler	86
(P) Kern	86
materials; Specific heats of various — Kiooshita	597
materials; Waterproof — (P) De Caudenberg	504r
purposes; Compositions for — (P) Gibb	86
purposes; Plastic compositions and slabs for — (P) Sperni and Burt	340
Buns; Determination of sugar in —	856
Burma; Cutch production in —	208
Wolfgram output of —	141
Burmese black varnish or lacquer	1018
Burners for blast-furnace gas, etc., for boilers, stoves, and like heating appliances, (P) Mackinlay	998
Gas — (P) Twomey	127r
Gas — for metallurgical and other furnaces, (P) Yates and others	1266
Liquid fuel — (P) Davls and Twigg	922r
for pulverised fuel, (P) Bergman	703

	PAGE
Burning fuel; Process of —:	
(P) Phil	205
(P) Rosenbaum, Stockbridge, and Borst	1267r
gas; Methods of — (P) Twomey	127r
gases; Process of — (P) Bone and others	588r
hydrocarbon vapours; Apparatus for generating and — (P) Leary and others	417
liquid fuel; Apparatus for — (P) Ellis, and Radiant Heating, Ltd.	379
pulverised fuel, (P) Caracristi, and Locomotive Pulver- ised Fuel Co.	998
Business names; Registration of —	199
Butane, iso-; Vapour pressure at low temperatures, and boiling point of — Burrell and Robertson	711
Butane; Vapour pressure at low temperatures, and boiling point of — Burrell and Robertson	711
Butter; Combined Reichert-Polenske and modified Shrews- bury-Knapp process for determination of coconut oil in — Elsdon	1103
Effects of feeding cottonseed products on composition and properties of — Eckles and Palmer	1144
fat; Detection of beef or mutton fat in — Seiden- berg	1138
Method of preserving — Paul	561
Process of renovating — (P) Eigelbner	232
The Shrewsbury and Knapp process for determination of coconut oil in — Elsdon and Bagshawe	400
substitute; Preparation of a — (P) Schortgenius	1246
substitutes; Nutritive value of — with reference to their content of the fat-soluble accessory growth sub- stance, Halliburton and Drummond	1285
<i>γ</i> -Butylene; Action of anhydrous aluminium chloride on — Gangloff and Henderson	956
Butyric acid; Separation and determination of — in biological products, Phelps and Palmer	567
Steam distillation of — alone and in admixture with acetic, propionic, or valeric acid, Richmond	519

Cacao; Composition of different varieties of — Brill ..	1245
Fermentation of Philippine —, Brill	1245
<i>See also</i> Cocoa.	
Cadmium; Iodometric determination of — Erierson	927
Separating zinc from —, Erierson	927
-tin alloys; Constitution of —, Bucher	652
Vapour pressure of —, Egerton	140
Cadmium compounds of the acridine series; Manufacture of — (P) Soc. of Chem. Ind. in Basle	867
nitrite, Rây	454
<i>Cesalpinia sappan</i> in the Philippines	706
Caffeine; Determination of — in cocoa and chocolate, Savini	98
Caiauei oil. <i>See</i> under Oils, Fatty.	
Cake and pastry order	479
Cakes; Determination of sugar in —	856
Calabar bean; Alkaloids of —, Polonovski	1193
Calcimines; Manufacture of — (P) Cornelison, and Cott-A-Lap Co.	1280
Calcining furnaces. <i>See</i> under Furnaces.	
Calcite-felspar; Fusion study of the mineral system —, Kirkpatrick	714
Calcium-aluminium alloy; Manufacture of — (P) Cooper, and Cooper Co.	655
and ammonia; Action of — on benzene, Dumanski and Zvereva	286
Function of — in the nutrition of garden pea seedlings with ammonium salts, Morosov	898
and magnesium; Separation of — in saline solutions, (P) Glaser	1245
Rapid determination of — in blood and milk, Lyman	561
Calcium acetate; Purification of crude — (P) Zinksen, and Fore Chemical Works	383
acetylsalicylate; Manufacture of — (P) Busch and others	615r
acetylsalicylate; Preparation of —, Bouvet	612
aluminate; Formation of tri- — in Portland cement, Campbell	1246
arsenate; Manufacture of — (P) Richter and Fiver bicarbonate; Determination of — in boiler-feed water, Monhaupt	160
bromide as a desiccant; Efficiency of —, Dover and Marden	995
carbide; Alcohol from — in Switzerland	492
carbide; Manufacture of an intermediate product for use in the manufacture of — (P) Alby	138
Carbide factories, and Hyland	1093
carbide; Restrictions on dealings in —	
carbonate; Determination of dissociation point of —, Montgomery and Groves	710
carbonate; Influence of — on determination of avail- able phosphoric acid in soils by Dyer's method, Sen, carbonate; Nitridation as a measure of availability of different forms of — when used as correctors of soil acidity, Burgess	723
carbonate; Production of bodies of extended, discontinuously associated solid particles of —, (P) Seigle, and Johns-Manville Co.	1280

(P) Stroband	1122 <i>r</i>
(P) Sturtevant Engineering Co.	24 <i>r</i>
(P) Watson	376
apparatus; Air shafts for —. (P) Dinesen	445
apparatus for asbestos and other materials. (P) Bourque	583
apparatus for fibrous materials. (P) Balzer, and Troy Laundry Machinery Co.	334
apparatus with moving wire band. (P) Schulze	584
apparatus for peat and the like. (P) Jenkins, and Peat Coal, Ltd.	536
apparatus of rotary chamber type. (P) Elsworth	536
apparatus; Vacuum —. (P) Taylor, and Shaw and Co.	995
apparatus for wattle bark, maize, or other like commodity. (P) Mitchell	996
bricks, retorts, and the like; Tunnel dryers for —. (P) Price	1236
chamber for alimentary pastes and other products. (P) Falchi	159
chambers for liquid, fluid, and moist materials. (P) Loebel	584
of cinematograph films and the like; Quick —. (P) Planchat	913
clay articles and apparatus therefor. (P) Secord and others	551
cloth or like porous and absorbent material; Suction-roll arrangements for —. (P) Hellström	1269
coated fabrics; Apparatus for — and recovering the solvent. (P) Hopewell	334
and conditioning yarn. (P) Sibson and others	383
and cooling nuts, cubes, etc., of cattle food and the like, and grain, seed, etc., in bulk; Apparatus for —. (P) Schueler	98
and cooling substances; Apparatus for —. (P) Hess	202
copra; Apparatus for —. (P) McCord	511
cotton, wool, rags, etc.; Dryer for —. (P) Solod	1126
drums. (P) Peters	584
explosives. (P) Phillips, and Du Pont de Nemours Powder Co.	1065 <i>r</i>
fruit, vegetables, herbs, chemicals, powders, seeds, minerals, and the like; Apparatus for —. (P) Hewitt	858, 1087
fruits and vegetables; Process and apparatus for —. (P) Beckworth and Hobson	903
glue-like material. (P) Mooney	1033
grain; Apparatus for —. (P) Staunton	415
with granular calcium chloride. McPherson	954
of hollow articles. (P) Williams and Bunch	1122
kilns. (P) Turner	537
liquids and the like. (P) Rigby and Testrup	447 <i>r</i>
lumber and other moisture-bearing substances; Dry-kiln for —. (P) Tiemann	889
machines:	
(P) Brownell and others	1227
(P) Sullnberger	415
machines for alimentary pastes. (P) Tegoli, and Tegoli Drying Apparatus Manufacturing Co.	351
machines for fabrics. (P) Allison and Sibson	1092 <i>r</i>
machines with rotary heating devices. (P) Simon	996 <i>r</i>
materials; Method of —. (P) Damon, and Allis-Chalmers Manufacturing Co.	583
materials such as pulverised reclaimed rubber. (P) Price, and Rubber Regenerating Co.	207
materials in sacks or the like; Apparatus for —. (P) Dinesen	1171
materials <i>in vacuo</i> ; Means for use in —. (P) Blyth and Miles	583

Cell-free — in alkaline solutions. Neuberg and Färber	515	sulphate; Conversion of — to ferric sulphate in wet extraction of ores. (P) Borchers and Boever	929
Changes undergone by cider during —. Hartman and Tolman	1024	sulphide; Heat of formation of —. Parravano and De Cesaris	595
Citric acid — of <i>Aspergillus niger</i> . Currie	975	Fertiliser composition; Manufacture of —; (P) Earp-Thomas and Hannah	397
of dextrose by yeast. Witenko	1283	(P) Lipman	1021
Prothy — of second jet massecuites and after-products in beet sugar factories. Gillet	899	constituents contained in cane molasses and vinasses; Utilisation of the —. Cross and Harris	897
Influence of addition of alanine on —. Ablerhalden	1283	Garbage-lumpage as a —. Schroeder	660
Influence of small and short elevations of temperature upon the progress of —. Richet and Cardot	97	Gypsum as a —. Nolte	1186
of maize silage; Relative influence of micro-organisms and plant enzymes in the —. Lamb	470	trials with tetraphosphate in Piedmont rice fields. Marelli and Novelli	897
of milic acid. Lebedev	390	Use of ground limestone as —. Burt-Davy	1200
of mixture treated with sulphur and sulphates. Changes in nitrogen and phosphorus content. Ames and Richmond	1020	Fertilisers; Artificial —. Their present use and future prospects. Russell	250
mixtures; Accurate aeration method for determination of alcohol in —. Dox and Lamb	42	from calcium nitrate and urea. (P) Badische Anilin und Soda Fabr	599, 569r
organisms; Preservation of — in nutrient media. Klöcker	975	Cleaning animal hair such as wool, and producing —. (P) McBride	450, 1092r
of Philippine cacao. Brill	1245	Committee on supplies of —	93
processes; Action of toluene on —. Buchner and Skraup	1189	containing ammonium magnesium sulphate and ammonium chloride; Manufacture of —. (P) Precht	398
products; Determination of succinic acid in —. Grey	978	containing superphosphate; Factors influencing the solubility of phosphoric acid in mixed —. Flack	897
of silage; Micro-organisms and heat production in —. Hunter	1060	Decomposition of raw phosphate material for manufacture of —. (P) Burth	398
Studies in —. Biedermann	230	Determination of phosphorus pentoxide in — after citrate digestion. Smith	40
of sucrose-phosphoric acid, and the sucrose-phosphate of yeasts. Djénab and Neuberg	1284	Effect of — on the composition and quality of oranges. Young	349
of sugar-cane juice. Kyser	1143	Effect of large applications of — on carnations. Beal	95
of sulphite-cellulose waste liquor. (P) Jernberg	561	Manufacture of —; (P) Detries	96
Fermented beverages; Manufacture of —. (P) Wahl-Henius Research Laboratory, and Wahl	936	(P) Haugley, and By-Products Reclaiming Corporation	934
beverages; Manufacture of non-intoxicating —. (P) Nowak	1285	(P) Messerschmitt	349
beverages; Treatment of —. (P) Schneide	1144	(P) Nash	898
Ferments, oxidising; Manufacture of diastases and toxins by —. (P) Boidin and Edouard	732r	(P) Pennewell	96
Ferric chloride and glacial acetic acid; Constitution of compounds formed by interaction of —. Weiland and Kessler	135	(P) Richardson, and Swift and Co.	934
chloride; Hot dialysis of —. Neidle and Barab	290	(P) Shields	398
ferricyanides; Colloidal —. Heller	871	(P) Zilk	1058
hydroxide; Adsorption of sulphuric acid by —. Dittler	1176	Manufacture of — in Australia.	1078
hydroxide; Behaviour of — towards egg albumin. Rakuzin	301	Manufacture of compound —. (P) Degide	1166r
oxide; Behaviour of — towards egg albumin. Rakuzin	301	Manufacture of — from lignite ash. (P) Fehn	299
oxide and alumina. Scheetz	1270	Manufacture of non-dusty — of uniform composition. (P) Winterfeld	299
oxide; Preparation of colloidal hydrated —. Neidle and Crombie	30	Manufacture of — from peat; (P) Bottomley	95
oxide; Rapid preparation of colloidal hydrous —. Neidle and Barab	290	(P) De Whalley, and Molassine Co.	566r
sulphate; Use of nitre cake in manufacture of crude — for sewage precipitation. Grisley	1216a	Manufacture of phosphate —. (P) Volpato	898
sulphide. Rott	82	Manufacture of — from refuse, sewage sludge, etc. (P) Purse	1143
Ferricyanides; Determination of — by titration with permanganate. De Coquet	1006	Manufacture of — from silicates. (P) Jackson and Horney	1021
Interference of — in the detection of iodides with palladium. Curtman and Harris	337	Manufacture of stable — from molasses. (P) Wilkening	96
Ferrification in soils. Brown and Corson	228	Manufacture of — from Steffens waste water, etc. (P) Herzka	398
Ferro-alloys; Manufacture of — in Australia	1077	Manufacture of — from sulphite-cellulose waste liquor. Kressel	730
Manufacture of — utilising waste heat from coke making. Peile	113	Maximum prices fixed for compound — from molasses. (P) Molassine Co., and others	1069
Ferro-cerium pyrophoric alloys.	373	nitrogenous; Ammonifiability versus nitrifiability as a test for relative availability of —. Lipman and Burgess	606
Ferrochrome; Determination of chromium in —. Herwig	341	nitrogenous; Availability of — in arid soils. Lipman and Gericke	229
Determination of chromium in — by permanganate method. Koch	552	Organic nitrogen compounds of —. Lathrop	559
Ferro-concrete ships	492	Plant-physiological study preliminary to the chemical analysis of —. Mitscherlich	397
Ferrocyanides; Interference of — in the detection of iodides with palladium. Curtman and Harris	337	for seeds and plants. (P) Barbieri	1244
Ferronanganese in the iron and steel industry. Anderson	649	Study of determination of potash in — especially by the Lindo-Gladding method. Hibbard	661
Manufacture of — in the blast-furnace from manganese ores rich in oxygen. (P) Lange	555	Utilisation of peat for —. (P) Waterbury, Ltd.	152r
Ferro-nickel; Production of —. (P) Robert	391	Volumetric or Penborton method of determining phosphoric acid in — and influence of temperature and of the sulphuric acid radical on the results. Shuey	514
Ferrophosphorus; Manufacture of —. (P) Gray	555	See also Manures.	
Manufacture of — from nelsonite. (P) Gray	597	Fertilising value of ammoniacal liquor; Improving the —. (P) Schubert	299
Ferro-silicon; Commercial analysis of —. Lowe	1237	Fibre, crude; Determination of —. Mangel, and Trowbridge	43
Manufacture of — and crystalline fused alumina. (P) Tone, and Carborundum Co.	1128	Marine —. Winterbottom	542
Manufacture of — of high silicon content in blast furnaces. (P) Johnson	928	parchmentised; Manufacture and treatment of —. (P) Diamond State Fibre Co.	1232r, 1232r
Metallurgy of —. Anderson	881	products; Manufacture of —. (P) McIntosh, and Diamond State Fibre Co.	1092, 1092
and silicon carbide; Deoxidation of iron and steel alloys by —. (P) Treutheit	928		
Ferrotungsten; Process of treating —. (P) McKenna	142		

	PAGE		PAGE
Fibre—cont.		Films; Apparatus for production of— from more or less	
vulcanised: Eliminating and recovering acids and salts		vulcanised material in bulk. (P) S&Sthagen and	996
from — (P) Tiffany, and Continental Fibre Co.	708	Bernhard	335r
vulcanised: Manufacture and treatment of — (P)	1232r, 1232r	Process for obtaining — (P) Leduc and Jacquemin	387r
Diamond State Fibre Co.	544, 1004r	Production of — (P) Lilliefeld	1088r
vulcanised: Treatment of — (P) Anders, and Roessler	212	Filter-bodies: Testing —	
Fibres, animal: Finishing — (P) Soc. Chem.	709r	(P) Zahn Manufacturing Co.	494
animal: Producing test tints on — (P) Soc. Chem.	709r	(P) Zahn, and Zahn Manufacturing Co.	329
Ind. in Basle		mediums: Cleansing — (P) Genter	736
Apparatus for boiling — for manufacture of cellulose	1015	Paper: Reducing matter extractable from —	700
(P) Ellis and Wilhelm	1087	McBride and Scherrer	535
Apparatus for drying — (P) Hewett	923	plates. (P) Greiner	1086
Preparing — for paper making. (P) Drewsen	591	presses:	
Production of aniline dyes on — (P) Mosley and		(P) Bridgshaw	377
McCardell		(P) Guerrero	585
Production of azo dyes on — (P) Beyer	81, 594	(P) Vallez	859
and Co.	335	presses: Cloth for — (P) Hanson, and Berlin Mills	585
Production of brown dyeing on — by oxidation. Diehl	335	Co.	377
Production of copper compounds of <i>o</i> -hydroxyazo dye-		presses: Continuous — (P) Sweeney	1053
stuffs on — (P) Soc. Chem. Ind. in Basle	282, 282r	presses for hydrometallurgical operations and method	
Production of fast dyes on — (P) Meister, Lucius,		of preventing oxidation of the filtrate in the con-	
u. Brünig	594	tainers thereof. (P) Mills, and Merrill Metallurgical	634r
Production of insulating material from — (P)	1041	Co.	536
Schewelin		presses: Treating semisolid material in the containers	
Recovering — from fibrous materials such as waste		of — and removing it therefrom. (P) Merrill	536

Formaldehyde—cont	
and phenols; Condensation products from — (P) Berend ..	317
and phenols; Manufacture of hard condensation products of — (P) Tarassoff and Shestakoff ..	538
and phenols; Manufacture of insoluble condensation products from — (P) Reeser ..	1185r
phenols, and salts of sulpho acids; Preparation of solid condensation products from — (P) Tarassoff and Shestakoff ..	159, 1055r
and potassium permanganate fumigant. Hill ..	41
as a product of the delignification of nitrocellulose. Trapani ..	907
Requisition of stocks of — ..	479
Formates; Manufacture of — (P) Katz and Ovlitz ..	385
Formic acid; Catalytic decomposition of — by rhodium. Haas ..	81
and cholic acid; Compound of — (P) Rietz, and Synthetic Patents Co. ..	473r
Manufacture of — (P) Bredig, and Koepf and Co. ..	1008r
Preparation of — from sodium cyanide. Bucher ..	453
Steam distillation of — Richmond ..	510
Formosa; Extraction of the colouring principle of indigo plants of — Katayama and Matsumoto ..	418
Foundry work; Electrical heating for baking of cores in — Hirschfeld ..	1102
Fourdrinier paper machine. (P) Davies ..	960
Fractionation of petroleum and other liquids. (P) Burleson and Prutzman ..	333r
of the products of distillation of a mixture of volatile liquids; Apparatus for the continuous — (P) Allan ..	127
France; Census of stocks of oils, fats, etc., in — ..	983
Chemical and allied industries in — during the war. Le Maistre ..	476
Importation of resin from — ..	1151
Imports into — ..	812
prohibited exports ..	619
Frangula; Identification of — Beal and Okey ..	565
Freezing fish and other food substances. (P) Dahl ..	1145
French chemical manufactures; New — committee to control chemical, pharmaceutical, and photographic products, colours, perfumes, etc. ..	983
<i>French rhomboidea</i> ; Essential oil of — Singh ..	1191
Friedel-Crafts' reaction. Decomposition of polyalkylbenzenes. Baedeker and Halse ..	129
Fructose. See <i>Lævulose</i> .	
Fruit juices; Preparation and preservation of — (P) Cheney ..	351
Fruits; Acid content of — Bigelow and Dunbar ..	1025
Apparatus for drying — (P) Beckworth and Hobson ..	903
(P) Hewett ..	858, 1087
Conversion of — into dried products. Valvassori ..	159
Preserving — (P) Von Eppler ..	1061
Preserving — fresh. (P) Franks ..	938
Process for drying — (P) Beckworth and Hobson ..	903
Fucose; <i>p</i> -Tolylhydrazine of — Van der Haar ..	662
Fuel. (P) Hermann ..	956
Apparatus for distilling — (P) Wallmann ..	206
artificial; Furnaces for peeping — (P) Groom ..	25r
bituminous; Generator for producing producer-gas or water-gas mixed with distillation gases from — (P) Dolensky ..	380
briquetting plant. (P) Rigby, and Waterbonding, Ltd. ..	77r
Carbonising — (P) Doherty ..	76
composition; Manufacture of a liquid — (P) Swanberg and Fisk ..	637
Conversion of waste products of — into inflammable gas for consuming smoke in furnaces. (P) Shilland others ..	861
for domestic and industrial use. (P) Fachini ..	1124
and fire-lighter; Composition — (P) Smirk ..	447r
-gas; Production of — (P) Sklovsky, and Deere and Co. ..	862
from gas works; Industrial — Smith ..	758
gaseous; Calorific value of industrial — Pickering ..	762
for high-speed internal combustion engines; Production of motor — (P) Hill ..	333r, 862
Hydrocarbon — for internal combustion engines. (P) King and Stoneham ..	1280
for internal combustion engines; Apparatus for straining oil — (P) Cannell Laird and Co., and Carter ..	553
for internal combustion engines; Carburetting air to form a gaseous — (P) Dyer ..	957
for internal combustion engines; Combining liquid hydrocarbons to render them suitable as fuel for — (P) Stoneham ..	1173
for internal combustion engines; Liquid — (P) Hannin ..	588
for internal combustion engines; Manufacture of gaseous — (P) Southey ..	637
Liquid — (P) Hill ..	1125

Open-hearth regenerative — (P) Clyde Furnace Co. (A), Ltd., and Dixon	37, 887
Operating producer-gas-fired — (P) Doherty	445
Ore-roasting —	
(P) Bowman, and Grasselli Chemical Co	1052
(P) Whittin	555
for preparing artificial mel. (P) Groom	25r
for production of oxygen from atmospheric air. (P) Ross and Edwards	215
Puddling — (P) Ford	340
for pulverous fuel — (P) Von Pont	858
for purifying zinc. (P) Ziesing, and Grasselli Chemical Co.	1052
Rabbling appliances for mechanical ore-roasting — (P) Harris	89r
for recovery of easily fusible metals from scrap; Continuous — (P) Gauschemann	601
for reducing ores. (P) Aarts	1000
for refining metals. (P) Kermod and Miller	1052
Refuse — (P) Kidwell, and Waste Utilities Co. of Delaware	1147
Regenerative — (P) Smythe, and Smythe Co.	585
Regenerative — for annealing and like purposes. (P) Stevens	537
regenerative; Reversing valves and flues for — (P) Percival	996
Retort — for preparation of hydrogen from iron and steam. (P) Naher and Noding	593
Reverberatory; Means for heating — (P) Tync Glass Works, Ltd., and Roxburgh	1129
Roasting —	
(P) Fougere	132
(P) Livingston	1240
for roasting cement, magnesite, etc. (P) Beocsimi Cementgyári Unio Részvényársaság	964
roasting; Rabblers for mechanical — (P) Hommel	509, 930r
for roasting zinc blende. Ridge	677
Rotary — for manufacture of carbon from vegetable matter (P) Sumner	1000
shaft; Feeding mechanism for — (P) International Construction Co., and Sahlin	862
Smelting —	
(P) Kirby and others	600
(P) Lundberg	1013
(P) Moses	291
(P) Poulson and Mate	1239
(P) Ruck	601r
(P) Verein. Hüttenwerke. Birkach-Eiche-Düdelingen A.-G.	1100
smelting; Adapting carbon residues from petroleum distillation for use in — (P) Kendall and others	1052
smelting; Oil or gas burning — (P) Moore	655
for smelting ores. (P) Beaver and Claremont	1278r
for steam generators. (P) Heyl	857
of steam generators; Use of pulverised fuel in — (P) Robinson	1123
Steel-making and like — (P) Wellman, Seaver, and Head, Ltd., and Gray	597
steel; Refractories for — from the consumer's point of view. Brooke	1273
Tank heating — (P) Springeour, and Mires Fuel Oil Equipment Co.	77
Tilting —	
(P) Hall	121r
(P) Price	557r
Tilting or rolling — (P) Campbell, and Soc. Electro-Métallurgique Française	115r
for treatment of spent iron oxide. (P) Kershaw	1004
for treating steel. (P) Archer	222
Tunnel — (P) Stein et Cie.	1263
Tunnel muffle — for burning ceramic ware, and heating metals, chemicals, and other materials. (P) Padelt with vertical retorts and producers beneath the retorts. (P) Lengersdorf and Co.	636
wire-bar; Vaporisation of copper in — Butts	221
Zinc — (P) Lonsdale and Rogers	343
Zinc-smelting — (P) Heeger and others	887
Fused materials; Preventing so-called "cold-blowing" in atomising — (P) Metallatom Ges.	75
Fusel oil; Manufacture of — from petroleum. (P) Hilbert and others	403
oil substitute; Manufacture of — from gasoline. (P) Brooks and others	569
Fusible substances; Production of coatings of — (P) Stolle	294
Fusing; Furnaces for — (P) Grocott	1240

G

Gahctobiose; Biochemical synthesis of a second — by means of emulsin. Bonquetot and Aubry	515
Gahctose; Determination of free and combined — Van der Haar	155
Variations in rotary power of — in aqueous propyl alcohol of different concentrations. Foulkes	41
d-Gahctose; o-Tolylhydrazine, a sensitive reagent for — Van der Haar	1022
p-Tolylhydrazon; of — Van der Haar	662
Galena as an ingredient of glazes. Miller	878
Galical preparations; Determination of mercury in — Wastenson	1194

Galletta, Ontario; Lead mining and smelting at — Newnam	599
Gallium; Electrolysis of — Uhler	141
Qualitative separation and detection of — Browning and Porter	1109
Galloyanines. See under Oxazine dyestuffs.	
Galvanic batteries and cells. See Electric batteries and cells.	
Galvanised iron. See under Iron.	
Galvanising process. (P) Watrous, and Watrous Galvanizing Co.	536
small articles; Mechanical process for — (P) Ziegler	144
wire; Furnace for — (P) Meaker	144
Garbage; Manufacture of alcohol from — (P) Young tankage; its composition, availability of its nitrogen, and its use as fertilizer. Schroeder	669
Gas absorption apparatus; Simple and efficient — Richmond and Hembrough	317
analysing apparatus; Gas filters for — (P) Aktiebolaget Ingeniörsfirma Egnell	980
analysing plant. (P) Aktiebolaget Ingeniörsfirma Egnell analysis; Apparatus for — (P) Aktiebolaget Ingeniörsfirma Egnell	166, 404r
Apparatus for generating — (P) Marvin	1147
Apparatus for making — from liquid hydrocarbons. (P) Dayton	379
Apparatus for manufacture of —	
(P) Begeemann and Gindke	447
(P) Doherty, and Improved Equipment Co.	998
Benzol recovery from — Wilson	24
blast-furnace; Apparatus for purifying — (P) Fellmann and others	380r
blast-furnace; Burners for — for boilers, stoves, and like heating appliances. (P) Mackinlay	998
blast-furnace; Limits of complete inflammability of mixtures of — with air. Burrell and Gauger	955
blast-furnace; Preheating — (P) Oesterlen	510
burners. (P) Twomey	127r
burners for metallurgical and other furnaces. (P) Yates and others	1266
-calorimeter; Continuous — (P) Breyer, and New Jersey Zinc Co.	102
coal; Action of — on green plants. Wehner	1195
coal; Action of — whilst passing through soil or water, on roots and leafy branches. Wehner	1187
coal; Ammonia recovery from — and intensive scrubbing. Blauvelt	125
coal; Apparatus for determination of benzol and toluol in — Copp	378
coal; Apparatus for manufacture of —	
(P) Carroll	126
(P) Riter-Conley Manufacturing Co.	126
(P) Waddell	127r
coal; Apparatus for vaporising oils for enriching — (P) Mackinlay	998
coal; Benzol recovery from — by a modified dehydrating plant. Keable	586
coal; Determination of light oils in — and still for separating the light oils from the absorbing oil. Duval	25
coal; Determination of naphthalene in — Knublauch	702
coal; Extracting vaporous constituents from — Lessing	103
coal; Extraction of hydrocarbons from — (P) Darier	126
coal — as fuel for melting non-ferrous alloys. Brook	322
coal; Liquid purification of — Espenhahn	483
coal; Manufacture of — (P) Waddell	127r
coal; Oil washing for recovery of benzene and toluene from — Adam	331
coal; Physico-chemical considerations on benzol recovery from — Read	331
coal; Preparation of — for storage in iron vessels under pressure, for incandescence lighting. (P) Fintsch A.-G.	921
coal; Removal of carbon bisulphide from — Wanner	75
coal; Removal of hydrogen sulphide from — (P) Krizko	646
coal; Toluene extraction from — Applebee	635
coal; Treatment of — (P) Riter-Conley Manufacturing Co.	25r
coke-oven; Treatment of — (P) Brown, and Rombacher Hüttenwerke	205
cold-proof; Manufacture of — (P) Elfred and Mercereau	999
condensers. (P) Vanston	25
cooler and washer. (P) Christopher	332
cooling apparatus;	
(P) Balassa and Hungarian Banking and Trading Co.	77
(P) Christopher	380
cylinders; Oxidized hydrogen gas explosions in compressed — Wöhler	917
"double"; Manufacture of — Strach	631
drying apparatus. (P) Balassa, and Hungarian Banking and Trading Co.	77
engine cylinders; Removing carbon from — (P) Rogers and others	77
engine system; Producer — (P) Bradley	389
engines; Utilisation of waste heat of — (P) Semmler	998, 995

Gas—cont.	PAGE
filtering apparatus. (P) Brooks and others	1171, 1171r
filters for gas analysing apparatus. (P) Aktiebolaget Ingeniörsfirma Egnell	980
firing and the glass industry. Cobb	1272
firing; New system of —. Jönides	1040
fuel; Production of —. (P) Sklovsky, and Deere and Co.	852
furnaces; Design and manipulation of —. Forshaw	1264
generating apparatus; Manipulating mechanism for coal —. (P) Riter-Conley Manufacturing Co.	25r
generation; Process of —. (P) Rider and Levien	447
generators:	
(P) Kilner Bros., and Knowles	1124
(P) Tinsley and Nash	636
generators; Device for preventing escape of gas from —. (P) Stein et Cie.	1173
generators; Electrodes for electrolytic —. (P) Levin	1241
generators; Electrolytic —:	
(P) Euler	1053
(P) Levin	391, 511, 1279r
(P) Schille	602, 892
high-pressure; Metal melting by means of —. Walter	322
hydraulic means used in the manufacture of —. (P) Drakes, Ltd., and Drake	1121
illuminating; Action of — on plants. Action of the gas on germination of spores and seeds. Wehmer	1021
illuminating; Apparatus for extracting tar, tar vapours and the like from —. (P) Scott and others	1125
illuminating; Effecting removal of carbon deposits from retorts for manufacture of — from coal. (P) Bark	861
illuminating; Limits of complete inflammability of mixtures of — with air. Burrell and Gauger	955
illuminating; Recovery of a volatile inflammable liquid in manufacture of —. (P) Greer	1041
industry; Most economical method of carbonising coal for supplying light, heat, and power by the — and the maximum supply of munitions of war. West	1265
industry; Research and standardisation in connection with refractory materials for the —. (P) Wolf	953
liquefied; Apparatus for producing —. (P) Webb	1263
liquor; Destruction of concrete by —. Dill	539
liquor; Increasing the manurial value of —. (P) Schubert	607r
liquor works; Report on — by the Alkali Inspector	991, 992
making; Peat, wood, and lignite in —	701
making; Substitutes for coal in —	1123
making; Wood in —	538
mantles. See under Incandescence.	
Manufacture of —:	
(P) Buch	862
(P) Carroll	123
(P) Doherty, and Improved Equipment Co.	998
Manufacture of — and of aromatic bodies from petroleum oils. (P) Mann and others	332
Manufacture of combustible —. (P) Doherty	76
Manufacture of — from liquid hydrocarbons. (P) Dayton	137
Manufacture of — from peat, lignite, or wood. (P) Rasmussen	1230
Manufacture; Production and prevention of naphthalene in —. Miller	1229
Manufacture; Sardinian lignites in —. Pechioni	378
meter; A laboratory —	52
meters; Report of Joint Committee of Institution of Gas Engineers and Society of British Gas Industries on life of —	702
Methods of burning —. (P) Twomey	1277
natural; Aromatic hydrocarbons from thermal decomposition of condensate from —. Zinetti and Ezloff	635
natural; Gasoline from — in the United States	1123
natural; Limits of complete inflammability of mixtures of — with air. Burrell and Gauger	955
natural; Preparation of lower chlorides of methane from —. Bedford	46
natural; Separating hydrocarbons from —. (P) Felt, and Petroleum Products Co.	380
nozzles; Controllable and removable air and — for coke-ovens and analogous devices. (P) Bagley	1266
Official method used by the Paris Municipality for measuring the calorific power of —. Girard and Lauriol	331
oil; Chlorination of —. (P) Brooks and others	1064
oil; Producer for —. (P) Nordensson	447
oil; Production of granular carbon from refuse from manufacture of —. (P) Pike	127
oil; Purification of —. (P) Tinker	998
oils; Cracking of — in various atmospheres. Downing and Pohlman	125
Power — obtained by low temperature carbonising. Maclaurin	620
Preserving —. (P) Alsop, and Alsop Electrical Co.	519
under pressure; Cementation of iron by —. Langenberg	530
producer; Generator for producing — mixed with distillation gases from bituminous fuels. (P) Dolensky	380
producer; Manufacture of — from powdered coal. (P) Bell	636
producer; Operating furnaces fired with —. (P) Doherty	445

Gas—cont.	PAGE
producer plants:	
(P) Dolensky, and Dellwik-Fleischer Wassergas Ges.	380r
(P) Whitefield	588
producer plants; Heat interchangers for —. (P) Lynn and others	1040
producer; Production of a diffused flame with —. (P) Doherty	126
producer; Treatment and recovery of tar and ammonia liquor from —. (P) Moore	332r
Producer —, and utilisation of coke dust or other low-grade fuel. Chaney	446
producers:	
(P) Bricknell and Burl	636
(P) Burger, and International Harvester Corporation	862
(P) Cousin	77r
(P) Dreflein	1266
(P) Glover and West	127r
(P) Hampden Cloncurry Copper Mines, Ltd.	447
(P) Herrick	206
(P) Isley, and Morgan Construction Co.	540
(P) Jafferries, and Morgan Construction Co.	1121
(P) Kihner Bros., and Knowles	1121
(P) Lynn and others	379
(P) Moffat	957
(P) Nelson	25r
(P) Nimphius and Whitaker	636
(P) Sahlin	957
(P) Stewart	77r
(P) Thuman	125
(P) Tully and Yeo	1121
(P) Tyne Glass Works, Ltd., and Roxburgh	957
producers; Charging apparatus for —. (P) International Construction Co., and Sahlin	862
producers; Feeding mechanism for —. (P) International Construction Co., and Sahlin	862
producers and furnaces; Combined —. (P) Bishop	862
producers of the Mond type; Method of working —. (P) Chadwick and others	127r
producers for retort settings; Internal versus external —. Smith	760
producers; Transferring coke from gas retorts to —. (P) Riter-Conley Manufacturing Co.	332r
producers; Working of by-product-recovery —. (P) Rigby and others	1090
Purification of —. (P) Felt	1089
purification oxides. Scott	496
purification. Sulphiding of hydrated oxide	997
others. (P) Reese	1125
purifying mass; Production of — and of hydrogen and Glauber salts from iron scrap and sodium bisulphate (P) Bequevort and Deuzile	962
reactions; Apparatus for effecting endothermic — by means of an electric arc. (P) Currie	656
reactions; Carrying out chemical — by aid of a diffuse electric discharge. (P) Andriessen	602
Recent developments in the industrial application of town's —. Walter	769
Recovery of ammonium chloride in manufacture of —. (P) Myers, and Shelton Iron, Steel, and Coal Co.	497
retort bench; Vertical —. (P) Plantinga	862
Retort-setting for manufacture of coke and —. (P) Koppers	285
retort settings; Internal versus external producers for —. Smith	760
retorts. (P) Plantinga	1124
retorts; Apparatus for charging and discharging —. (P) Riter-Conley Manufacturing Co., and others	206r
retorts; Charging of —. (P) Riter-Conley Manufacturing Co.	206r, 922r
retorts; Charging machines for —. (P) Riter-Conley Manufacturing Co.	127r, 285r
retorts; Hydraulic means used in connection with —. (P) Bloor and Fenwick	938
retorts; Machines for discharging and charging —. (P) Guest and others	206r
retorts; Transferring coke from — to gas producers. Riter-Conley Manufacturing Co.	332r
retorts, vertical; Distillation process in —. Teune and Kummel	331
retorts, vertical; Experiments on steaming in continuously operated —. Blundell	1172
retorts, vertical; Furnaces with — and producers beneath the retorts. (P) Leugersdorf and Co.	636
retorts, vertical; Heating of —. (P) Strassmann	956
retorts. See also under Retorts.	
Separating hydrocarbons from —. (P) Felt, and Petroleum Products Co.	380
In solution; Sealing glass bulbs containing a —. (P) Loepfinger, and General Fire Extinguisher Co.	1177
from straw. McLaurie	1265
Substitution of — for petrol and petroleum	1202
suction; Shells of generators for —. (P) Bellamy and James	332
superheaters. (P) Tasker	955
testing apparatus. (P) Webster	980
traction committee	1202
tri; Manufacture of — from coal. Naumann	538
under high pressure; Apparatus for condensing —. (P) Cabot	634

Gas—cont.	PAGE	Gases—cont.	PAGE
Valves for controlling, reversing, and by-passing the flow of — through scrubbers, purifiers, condensers, and the like. (P) Dempster and Sons, and Horstall ..	1264r	distillation; Generator for producing producer-gas or water-gas mixed with — from bituminous fuels. (P) Dolensky.	380
volumeter; A universal —. Denning	1248	distillation; Purification of — from coal. (P) Ciselet and Deguide	637
washer for determining the content of benzene, toluene, etc., Rhead	767	Electrical apparatus for extracting dust from —. (P) Gallot and Poussin	1263
washers and like apparatus. (P) Davis	447	Effusion method of determining density of —. Edwards	944
washing apparatus. (P) Balassa, and Hungarian Banking and Trading Co.	77	Electrical method and apparatus for separating constituents of or materials suspended in —. (P) Schmidt	1102r
washing apparatus; Artificial pumic stone as filling material for —. Hempel	200	Electrical recovery of certain constituents from —. (P) Schmidt and others	38
washing for benzol and toluol; analysis of products; control of stills. Edwards	539	Electrical precipitation of suspended particles from —. (P) Schmidt	1103r
water-; Apparatus for equalising the pressures in the producer and in the space below the grate of water-sealed producers for —. (P) Spitzer	921	Eliminating odours from —. (P) Eisendrath	303
water-; Continuous production of —. (P) Holmgren and others	921	Filling material for apparatus for cooling —. (P) Darier	1176
water-; Generator for producing — mixed with distillation gases from bituminous fuels. (P) Dolensky ..	380	Filling material for apparatus for washing of — by liquids. (P) Darier	1170
water-; Operating carburetted water-gas plants for production of blue —.	920	Fractional combustion of —. Bancroft	1172
water-; Preparation of hydrogen from —. (P) Wussow	330	furnace-; Filtering medium for cleaning —. (P) Kling and Weidlein	586r
water-; Treating materials for production of —. (P) Hornsey, and General Reduction Gas and By-Products Co.	285r	furnace-; Removal of dust from —. (P) Bingham from heat engines; Utilisation of heat of exhaust —. (P) Mitchell	1086
works; Benzol extraction in —. Clegg	1229	hydrocarbon; Improving the quality and yield of —. Davidson and Ford	862
works; Benzol recovery in —. Bagley	24	hydrocarbon; Purifying and improving —. (P) Starke and others	77
works; Industrial fuel from —. Smith	758	Instrument for recording percentage volumes of constituent —. (P) Crossweller	908r
works; Recovery of toluol in —.	1265	Limits of complete inflammability of mixtures of mine gases and industrial — with air; Burrell and Gauger	955
works retort carbon.	75	and liquids; Apparatus for effecting intimate contact of —. (P) Kirkham, Hulett, and Chandler, and Hersey and liquids; Devices for transference of heat between —. (P) Sawyer and Ilston	581
Gaseous fuel; Calorific value of industrial —. Pickering ..	762	and liquids; Mutual treatment of —. (P) Coombs ..	494
fuel for internal combustion engines; Carburetting air to form a —. (P) Dyer	957	Means for producing discharge of electricity into —. (P) Schmidt, and International Precipitation Co. ..	38
fuel for internal combustion engines; Manufacture of —. (P) Southey	637	"noble"; Apparatus for determination of — when mixed with nitrogen. (P) Brandt	616
mixtures; Complete combustion of —. (P) Ionides ..	206	noble; Purification of —. (P) General Electric Co.	1088
mixtures; Limits of inflammability of —. Thornton ..	283	Obtaining hydrocarbons from —. (P) Linderborg and Scott	498
mixtures; Proportioning of —. (P) Ionides	126	from Portland cement, lime, and other kilns; Apparatus for utilising waste —. (P) Schott	1009
mixtures; Separation of the constituents of —. (P) Claude, and Soc. l'Air Liquide	330r	power-; Composition of —. Tookey	309
mixtures; Temperature of ignition of —. McDavid ..	1264	Process of burning —. (P) Bone and others	588r
reactions with air rich in oxygen; Process for carrying out —. (P) Norsk Hydro-Elektrisk Kvaestofaktieselskab ..	215	Process for oxidising —. (P) Schmitz	1234
Gases: Absorption of —. Hempel	199	Producing cold by liquefaction of —. (P) Jefferies and Norton	858
Absorption of — by petroleum. Coste	954	Purification of —. (P) Claude, and Soc. l'Air Liquide	330
acid; Condensation, absorption, and other chemical treatment of —. (P) Charles and Lancaster ..	962	(P) Gidden	646
Apparatus for cooling —. (P) Josse and Gensecke ..	860r	Purification of — by the dry method. (P) Grosse ..	586
Apparatus for cooling and purifying —. (P) Humphries	83	Reactions between —. (P) Lacy	163
Apparatus for impregnating liquids with —. (P) Pindstoffe	124r	Recovery of hydrogen sulphide and hydrogen cyanide from crude —. (P) Behrens	593
Apparatus for indicating composition of —. (P) Haupt and Werner	522	Removing sulphur dioxide from —. (P) Eastis ..	389
Apparatus for indicating the volumetric flow of —. (P) Werner	1066	Separating certain constituents from —. (P) Bradley and others	538
Apparatus for liquefying and separating —. (P) Mewes	457	Separating — from liquids. (P) Walker	917
Apparatus for oxidising —. (P) Schmitz	1234	Separating mixed —. (P) Norton	859
Apparatus for purifying —. (P) Bartl	585	Separation of — by diffusion. (P) Wussow	330
(P) Zschecke	700	Separation of dust particles and smoke from —. (P) Baldwin	495
Apparatus for purifying, cooling, and mixing —. (P) Theisen	201	Separation of tar and condensable products from —. (P) Hannemann	588
Apparatus for refining —. (P) Wingett and Haggott ..	862	Simple apparatus for washing —. Gray	474
Apparatus for removing suspended matter from —. (P) Doherty	445	smelter-; Determination of sulphur dioxide in —. Sweeney and others	1233
Apparatus for separating liquids from —. (P) British Thomson-Houston Co., and others	1228	Specific gravity balance for —. Edwards	944
Apparatus for separating tar, tar vapours, and the like from —. (P) Scott and others	1215	Stepped ignition of —. Wheeler	378
Apparatus for separating vapours from —. (P) Frohlieb	585	Storing of — under pressure. (P) Acetylene Illuminating Co., and Stephenson ..	704, 860r
Apparatus for treating chaff and other loosely aggregated materials with —. (P) Renshaw	537	(P) Acetylene Illuminating Co., and Whibley ..	704
Apparatus for treating and cooling —. (P) Heenan and Fronde, Ltd., and Cruyt	1171	Treatment of liquids with —. (P) Killar	957
Apparatus for treating liquids with —. (P) Ittner ..	1228	Treatment and recovery of tar and ammonia liquor from —. (P) Moore	332r
Apparatus for vaporising oils for enriching —. (P) Mackinlay	998	Gasoline; Construction and operation of a single tube cracking furnace for making —. Bowie	285
atmospheric; Absorption of — by water. Coste	846	Effect of temperature and the time factor in the formation of — in the gas phase at constant pressure. Egloff and others	25
Automatic regulation of temperature of —. (P) Parkyn	201	filter. (P) Storm	999
boiler; Apparatus for washing and utilising waste —. (P) Sargent and others	995	Manufacture of —. (P) Davidson	1090
from coke ovens and the like; Treatment of —. (P) Roberts	205	(P) Smith and Milliken	1125
combustible; Apparatus for detecting presence of —. (P) Philip and Steele	672r	Manufacture of alcohols from —. (P) Brooks and others	569
Combustion of mixed —. (P) Bone and others ..	588r	from natural gas in the United States	1123
Compressing —. (P) Soc. Ital. di Elettrotecnica, and Bianchini	872	Obtaining — from heavier hydrocarbons. (P) Jenkins and Jenkins Petroleum Process Co.	704
Compressing, purifying, drying, and cooling —. (P) Felt, and Petroleum Products Co.	380	substitute. (P) Rice	921
Converting heavy hydrocarbons into light hydrocarbons or hydrocarbon —. (P) Synthetic Hydro-Carbon Co.	957	Synthetic — by electrochemical means. Cherry	1266
		vapour and air; Limits of complete inflammability of mixtures of —. Burrell and Gauger	955

Porcher and Dage	1107
Apparatus for pasteurising and like treatment of —. (P) Zeuthen and Larsen	1286
artificial; Manufacture of — and treatment of the residues. (P) Melhuish	1607
Chemical changes produced by addition of lime-water to —. Bosworth and Bowditch	231
and cocoa; Food compositions containing —. (P) Kitchen	937
Condensed —. De Rothschild and Porcher	609
condensed, evaporated, or concentrated; Definition of and standards for —	516
from cows and sheep; Distribution of fatty acids in fat of —. Crowther and Hynd	1059
cultures; Substitute for litmus for use in —. Clark and Lubs	976
Detection of added water in — by means of a simplified molecular concentration constant. Ferris	1245
Distribution of phosphatides in —. Osborne and Wakeman	158
dried; Definition of and standards for —	516
dried; Manufacture of —:	
(P) Campbell and Borden's Condensed Milk Co.	1025
(P) Hamburger und Co.	619
dried skimmed; Definition of and standards for —	516
malting; Definition of and standards for —	516
Manufacture of food compositions from —. (P) Wiley	937
Manufacture of products from —. (P) Gray	517
Means for desiccating —. (P) Booth and others	1170
Method of treating —. (P) Campbell and Borden's Condensed Milk Co.	563
powder; Determination of moisture and fat in —. Porcher	400
powdering machine. (P) Felleman	1145
Process of drying —. (P) Koeb, and Crystallized Milk Co.	1061
products; Determination of fat in certain —. Francis and Morgan	1144
products; Self-preserving acid — and process of making them. (P) Gröck	937
Rapid determination of calcium in —. Lyman	561
skimmed; Apparatus for production of compounds of vegetable fats and —. (P) Enz	1236
sterilising apparatus. (P) Rogers and Fremlin	1191
Study of reductases with a view of determining a method for the differentiation of pasteurised milk from raw —. Lee and Mellon	516
substitute made from soya beans and arachis nuts. (P) Melhuish	12377

machines for substances sensitive to pressure and friction; Vacuum —. (P) Wilhelmi	202
and measuring device. (P) Olney	609
mill; Continuous —. (P) Crossley	918
powdered substances, such as explosives, etc. (P) Dalton	1087
slimes by means of compressed air. (P) Polysius	699
and spraying liquids. (P) Einmerich	700
Mocaya oil. <i>See under</i> Oils, Fatty.	
Moistening air and the like; Apparatus for —. (P) Jackson	1087
yarns; Apparatus for —. (P) Jacobson	1174
Moisture; Protecting powder and other hygroscopic substances from —. (P) Seville Manufacturing Co., and Sperry	2037
Molasses; Beet —: its composition and utilisation. Osborn	661
beet; Influence of raffinose in — on determination of sucrose by double acid polarisation or by inversion with invertase. Pellet	935
beet; Manufacture of fertilisers from waste liquors from desaccharification of beet —. (P) Herzka	393

	PAGE
Molasses—cont.	
beet-; Pentose content of —. Pellet	935
cane-; Determination of glucose in —. Pellet	467
cane-; Determination of reducing sugars in — and in the vineasses, for calculating the amount of sugar fermented. Pellet	467
cane-; Extraction of sugar from low-grade — by the Williams process. Williams	398
cane-; Utilisation of the fertiliser constituents contained in —. Cross and Harris	897
Colouring matter of —. St. Jozsef	230
Device for examining a sample of —. (P) Baldwin	96
Device for taking a sample of —. (P) Baldwin	96
Influence of amino-acids and glutamic acid in the estimation of raffinose and sucrose in — by the inversion method. Stanek	934
Manufacture of betaine from —. (P) Act.-Ges. f. Anilinfabr.	473r
Manufacture of fertilisers from —. (P) Molassine Co., and others	898
Manufacture of a stable fertiliser from —. (P) Wilkening	96
Nitrogenous colouring matters of —; Friedrich	1187
Stanek	935, 1187
residues; Manufacture of potassium salts from — in France	492
Molten material; Cooling — to obtain the solid in a finely-divided state. (P) Leitch	634r
products; Means for electrically promoting the discharge of — from a furnace or other apparatus. (P) Reid, and Patents Process Co.	891
Molybdates of cobalt-ammonium compounds; Use of — in determination of cobalt. Carnot	908
Molybdenite; Concentrating Canadian —. Claudet	599
and products therefrom; Trading in —	1249
Molybdenum coated with gold or gold-palladium alloy. (P) Fahrenwald	889
Coating — with noble metals. (P) Fahrenwald	1016
Determination of — by potassium iodate. Jamieson	355
ores in Tasmania	36
Production of alloys of — with highly infusible metals having oxides which cannot be completely reduced by hydrogen. (P) Podzusz	929
and products therefrom; Trading in —	1249
residues; Recovery of —. Lenher and Schütz	979
Separation of — from wulfenite. (P) Klock	509
tungsten alloys. Fahrenwald	460, (P) 1016
and vanadium; Treatment of ores containing —. (P) Pellegri	1014
Volumetric determination of — in steel. Travers	1097
Molybdic acid; Yellow deposit of hydrated — in ammonium molybdate solutions. Penfold	384
Monazite in Ceylon; Recent work on —	88
deposits in Ceylon	335
sands in Ceylon	1203
Mono-alkylated aromatic amines; Manufacture of —. (P) Morgan	207
Monoozo dyestuffs. See under Azo dyestuffs.	
Monochlorobenzene; Manufacture of —. (P) Contagne	129
Monomethylamine; Hypochlorite colour reaction of —. Shepard	27
Montan wax and its behaviour on distillation. Marcusson and Smelkus	510
Mordant liquors; Preparation of artificial ochre from iron —. (P) Sachse	206
Mordanting natural and artificial silk, cotton, linen, and other textiles by means of foam. (P) Soc. de Teinture et d'Apprêt Clavel, and Lindenmeyer	133, 641r
textile materials; Process for producing foam for —. (P) Clavel	80
Mordants on silk; Fixing iron —. (P) Gebr. Schmid	80
on textile fibres; Fixing iron —. (P) Schmid	384r
Morphine alkaloids; Investigation of —. Von Braun and Kiedler	233
Colorimetric methods for the estimation of very small quantities of —. Heiduschka and Faul	1287
group; Manufacture of compounds of alkaloids of — with barbituric acid derivatives. (P) Soc. of Chem. Ind. in Basle	979
Methyl derivatives of —. Mannich	1026
Microchemical distinction of — from codeine. Tunnann	45
Microchemical precipitation of — with zinc chloride-iodine solution. Tunnann	941
Titration and estimation of — with iodic acid. Rakshit	989
Mortar, cement; Mixing —. (P) Hochstrasser	649
Colorimetric determination of organic impurities in sand for —. Abrams and Harder	718
Manufacture of —. (P) Hay	1178
Manufacture of a compound for making watertight —. (P) Morikami	1009
Mixing —. (P) Becker	597
Production of metal coatings on —. (P) Sanders	35r
Motive fluid; Apparatus for generation of —. (P) Keller Mechanical Engraving Co.	379
Motor fuel; Manufacture of — in South Africa	1260

	PAGE
Motor—cont.	
fuel; Production of —:	
(P) Hall	1267
(P) Kilar	957
fuel; Production of — for high-speed internal combustion engines. (P) Hall	333r
fuel for use in high-speed internal combustion engines. (P) Hall	862
garages; Utilisation of waste oils from —. (P) Heyl	1266
oil; Production of — by heating lignite products under pressure. Fischer and Schneider	587
spirit. Annan	243
spirit; Production of — from heavy hydrocarbons. (P) Hall	1267
spirit; Production of — for high-speed internal combustion engines. (P) Hall Motor Fuel, Ltd.	127
Mould fungi causing deterioration of paper. Sée	449
fungi; Formation of starch-like substances by —. Boas	1024, 1285
Moulding gunpowder and similar mixtures. (P) Lersch	735
material; Manufacture of —. (P) McCoy, and Westinghouse Electric and Manufacturing Co.	894
Mouldings; Plastic composition for use in manufacture of —. (P) Tomahu	965
Moulds; Formation of starch-like substances by —. Boas	1024
Preservation of — in nutrient media. Klocker	975
Pure-culture apparatus for —. (P) Magné	399
Mucorini; Pure-culture apparatus for —. (P) Magné	399
Muffle furnaces; Tunnel — for burning ceramic ware and heating metals, chemicals, and other materials. (P) Padelt	633
kilns for enamels. (P) Schröder	596
Munitions Ministry; New branch of — for development of United Kingdom mineral resources	459
Muntz metal; Corrosion of brasses of type of —. Rawdon	1180
Muriatic acid. See Hydrochloric acid.	
Murumuru oil. See under Oils, Fatty.	
Muscicides; Experiments with —. Phelps and Stevenson	939
Muscovite; Action of ammonium sulphate solutions on —. Gardiner and Shorey	896
Musk; Artificial —. See Trimethyl-tert-butylidene.	
Musts; Preparation of —. (P) Disdier	608
Sulphurous acid in chemical combination in —. Laborde	935
Mydriatic alkaloids; Detection of —. Eder	941
Myristica platyperma, Spruce; Fatty oil of —. Bolton and Hewer	345
Myrosin; Absence of — in Berlin top and bottom yeast. Neuberg and Färber	1024

Nitrometer; Application of — to determination of constitution of nitro-compounds and estimation of nitrogen in nitro-amines, Cope and Barab	46
Nitromethane and homologues; Preparation of —, (P) Kraus	259
Nitron as gravimetric reagent for analysis of substances used in explosives, Cope and Barab	473
Nitrophenols; Manufacture of — from certain gums or gum resins, (P) Miller and Irlam	499
Nitrosamine colours; Production of azo dyestuffs from in multi-colour printing, (P) Chem. Fabr. Griseheim-Elektron	584
o-Nitrosamines; Conversion of — into iso-oxadiazoles, Green and Rowe	958
Nitroso-compounds; Reduction of — with platinum and hydrogen, Cushman	1267
Nitrosopyrrole Black, Angelo and Cushman	923
Nitrostarch; Manufacture of —, (P) Sadtler	238
Nitrotoluenes; Determination of —:	
Colver and Prideaux	856
Knecht	694
Preparation of —, Kikokoro	1065
Stannous chloride reduction method for estimating —, Colver and Prideaux	480
Nitrous acid and urea; Mechanism of the interaction of —, Werner	1147
Velocity of decomposition and dissociation constant of —, Ray and others	1175
Nitrous air; Antiseptic properties of —, Collin	977
gases; Production of —, (P) Landis and Washburn ..	1234
nitrogen in irrigated soils, Greaves and others	606
oxide; Vapour pressure at low temperatures, and boiling point of —, Burrell and Robertson	711
Nonyl methyl ketone from palm kernel oil, Salway	1184
Norfolk oil shales, Forbes-Leslie	204
Norway; prohibited exports	573, 1251
Nottingham Section. Discussion on nitre cake	1216A
Nucleates; Manufacture of —, (P) Bottomley	614
Nucleic acid derivatives; Isolation of — from yeast, Bottomley	1143
Manufacture of —, (P) Bottomley	614
of yeast; Mode of nucleotide linkage in —, Jones and Read	402
of yeast; Preparation of guanine mononucleotide (guanylic acid) from —, Read	978
of yeast; Structure of —, Jones and Read	402
Nucleic acids; Rotatory powers of —, Rakuzin and Brande	305
Nucleotide of guanine; The mono- —, and its preparation from yeast nucleic acid, Read	978
of uracil and cytosine; The di- —, Jones and Read ..	978
Nuts; Machines for expressing oils or liquids from —, (P) Schueler	1054

O.

Oat kernel; Nature of the dietary deficiencies of the —, McCollum and others	562
Oats restriction order	479

Obtaining material; Manufacture of —, (P) Marsden ..	1044
Occupations order; Restricted —	356
of primary importance; List of —	308
Ochre, artificial; Preparation of — from iron mordant liquors and clay, (P) Sachse	296

	PAGE
Ocotillo plant; Apparatus for treating the — to extract the gum. (P) Snyder and Crawford	1188
Odour and constitution; Relation between —. Prins ..	942
of the dichlorophenols and of their anisols. Hollemao ..	1001
Odours; Eliminating — from gases, fumes, etc. (P) Eisendrath	302
<i>Oenocarpus batava</i> ; Fatty oil of —. Bolton and Hewer ..	345
Oil; Apparatus for separating — from steam. (P) British Thomson-Houston Co. and others	1228
in brewing adjuncts and its effect on quality of beer. Dreesbach	1108
compositions; Colour concentrate for edible —. (P) Ellis	665
engines; Liquid fuel for high-compression —. (P) Heyl	1173
-fired melting furnaces and the like. (P) Hall	600
fuel; Furnaces heated by — for melting metals. (P) Ward and others	37
fuel for internal combustion engines; Apparatus for straining —. (P) Cammell Laird and Co., and Carter	585
-gas. See under Gas.	
industry; Fullers' earth and its valuation in the —. Richert	893
Rapid determination of — in malt and cod liver oil preparations. Richmond and Hitchman	273
seeds, Brazilian —. Bolton and Hewer	345
seeds and fruits; Census of stocks of — in France ..	983
seeds; Ministry of Munitions Order relating to — ..	478, 523
seeds and their products; Control of — by Ministry of Munitions	345
seeds; Restricted dealings in —	523
splitting order, 1917	1151
-tanning; Materials for —. (P) Röhm	1141
-treating device. (P) White and Baruhart	1268
used in a wooden mill; Note on a dangerous —. Fairley and Burrell	113
varnishes; Determination of volatile thinners in —. De Waele and Smith	603
-water emulsions; Apparatus for separating —. (P) Sands and Gourlay	698
of wine; Heavy —. Kremann	905
works; Recovery of solid constituents from waste liquors of —. (P) Hansen	397
Oils; Apparatus for decomposition of —. (P) Reuter, and Reuter Process Co.	723
Apparatus for dehydrating —. (P) Prutzman	1090
Apparatus for distillation of —: (P) Flatau	990
(P) Herber	704
Apparatus for expressing — from seeds and other materials. (P) Barton	1054
Apparatus for extraction of —: (P) Engel	893, 1018
(P) Strickland	1018
Apparatus for purifying industrial —. (P) Noël ..	1477
Apparatus for vaporising — for enriching coal and other gases. (P) Swindin	998
Bleaching —. (P) Reuter, and Reuter Process Co.	4637
Catalysts for hydrogenating —. (P) Itner	1139
Catalytic bleaching of —. Rai	948
Catalytic device for hydrogenating —. (P) Dewar and others	6037
Centrifugal separator for removing — from wood distillation vapours. (P) French	3337
Cleaning filters in connection with the purification of —. (P) Wooster	1121
Closed dash-point tester for —. (P) Tagliabue, and Tagliabue Manufacturing Co.	1031
in coal gas; Determination of light — and still for separating the light oils from the absorbing oil. Duvall	25
Converting heavier — into lighter oils. (P) Lampough	25
Decomposition of —. (P) Reuter, and Reuter Process Co.	511
Determination of unsaponifiable matter in —. Wilkie ..	723
Distillation of —: (P) Herber	704
(P) Heyl	380
Distillation of solvents from solutions of —. (P) Pooley, and Scott and Son	394
Extracting benzene from heavy —. (P) Barbet et Fils et Cie	7057
Extraction of —. (P) Barstow and Griswold	1103
and Fats Branch of Department of Explosives Supply, Ministry of Munitions	345
fuel; Straining or filtering apparatus for —. (P) Vickers, Ltd., and others	917
heavy; Process and apparatus for employing — and petrol in internal combustion engines. (P) De Ferry ..	8637
heavy; Production of toluol, benzol, and other light hydrocarbons from —. (P) Anderson and Meikle ..	1001
Hydrogenation of —: (P) Ellis	463
(P) Hagemann and Baskerville	1103
(P) Maxted and Ridsdale	1185
Light; Analysis of — for benzene, toluene, and xylene. Egloff	498

motor; Production of — by heating lignite products under pressure. Fischer and Schneider	587
obtained by low-temperature carbonising. MacLaurin ..	622
Oxidation of — in presence of soluble metallic catalysts. Mackey and Ingle	317
Preparing — for hydrogenation. (P) Dreyman	833
Process of cracking —. (P) Wells, and Ellis-Foster Co.	921
Process for refining —. (P) Parker, and Parker Process Co.	704
Production of — from bituminous materials. Ingram ..	1172
Rapid determination of suitability of — for soap making. Lecoq	723
Recovering — from "foots." (P) Hageman and Dieterich	1054
Recovery of hydrocarbons from absorbing —. (P) Koppers Co.	497
Refining saponifiable —. (P) Baskerville	1054
Removal of sulphur from —. (P) Evans, and South Metropolitan Gas Co.	267
Removing catalysts from —. (P) Ellis	723
Removing nickel from hydrogenised —. (P) Whitaker, and Southern Cotton Oil Co.	1241
Resistance of — to emulsification. Herschel	497
Restricted dealings in —	523
Revoluble retort for distilling —. (P) Herber	704
Separating water and other impurities from —. (P) Sands	237
Thermal values of —. The sulphuric acid or Maumene value. Marden and Dover	1138
Treating —: (P) Ellis	417
(P) McAfee	10007
(P) Snelling	207
Utilisation of aluminium chloride residues from refining of —. (P) McAfee, and Gulf Refining Co.	84
Vaporising — for use in high-speed internal combustion engines. (P) Hall	206
wash; Distillation of benzol, etc., from —, and still therefor. (P) Simon-Carves, Ltd., and Brown ..	1231
waste; Utilisation of — from motor garages. (P) Heyl	1266
Oils; Essential:	
Bay oil; Montserrat —. Tempany	613
Birch oil; Examination of sweet —. Ailbright	567
Camphor oil from Federated Malay States and from Mauritius	613
Cassia oil; Removal of lead from —. Schimmel and Co.	100
Cherry stone kernel oil. Rabak	159
<i>Cnidium officinale</i> oil. Sakai	613
Determination of — in citrus fruits. Wilson and Young	1247
<i>Eucalyptus Australiana</i> oil. Baker and Smith	352
Eucalyptus oil; Extraction of — from local plants at the Soukhoun Experiment Station, Caucasus. Kozlov ..	942
Extracting —. (P) Sheehan and McKay	238
Extraction of — from hops. (P) Welf	936
<i>Frenela rhomboidea</i> oil. Singh	1194
Geranium oil from British East Africa	1108
Indian —. Singh	1289
Influence of climatic conditions on composition of —. Pigulevski	295
Lemongrass oil from India	99
Lemon thyme oil from British East Africa	1108
"Oyster Bay" pine oil. Singh	1194
Peppermint oil; Effect of cultural and climatic conditions on —. Rabak	47
Production of — in British East Africa	1108
Rosemary oil from British East Africa	1108
Sherungulu tuber oil	100
Spike lavender oil from British East Africa	1108
Use of — as addition agents in plating baths. Mathers and Leible	1099
Wintergreen oil; Examination of —. Ailbright	567
Oils; Fatty:	
Anafá oil. Bolton and Hewer	346
Andiroba oil. Bolton and Hewer	346
Aouara palm oil. Bolton and Hewer	346
Arachis oil; Detection of — in admixture with olive oil. Biazzo and Vijdorek	90
Arachis oil; Detection of — in olive oil. Lund	722
Babassú oil. Bolton and Hewer	346
Batava oil. Bolton and Hewer	346
from Brazilian oil-seeds. Bolton and Hewer	345
Caiaué oil. Bolton and Hewer	346

Carapaoil. Bolton and Hewer	346
Castor oil; Action of nitric acid on —. Brightman	984
Castor oil; Extraction of — from seeds of local plants at the Soukhoom Experiment Station, Caucasus. Kozlov	942
Castor oil; Notes on the splitting of —. Jones	359
Castor oil prices; Ministry of Munitions order relating to —	673
Castor oil used for lubricating aeroplane motors; Detection of foreign oils in —. Frabot	1279
Cayeté oil. Bolton and Hewer	346
Census of stocks of — in France	983
Cherry stone kernel oil. Rabak	159
Cherry stone oil. Rabak	159
Coconut oil; Combined Reichert-Polenske and modified Shrewsbury-Knapp process for determination of —. Elsdon	1103
Coconut oil; Differentiation of — from palm-kernel oil in mixtures. Elsdon	1103
Coconut oil fatty acids; Utilisation of — for feeding purposes. Lauder and Fagan	1069
Coconut oil; The Shrewsbury and Knapp process for determination of — in butter and margarine. Elsdon and Bagshawe	400
Cod liver oil; Rapid determination of oil in preparations of milt and —. Richmond and Hitchman	273
Cokerite oil. Bolton and Hewer	346
Control of — by Ministry of Munitions	345
Cottonseed oil; Incomplete hydrogenation of —. Moore and others	657
Crab oil. Bolton and Hewer	346
Curu oil. Bolton and Hewer	346
Drying oils; Manufacture of non-saponifiable, unsaturated hydrocarbon oils from —. (P) Brooks and others	558
Drying oils; Substitutes for — as a medium for paints, varnishes, and impregnating agents. (P) Röhm	296
Dugong oil; Chemical examination of Australian —. Challiner and Penfold	192
Fish-liver oils; Natural occurrence of high percentages of hydrocarbons in certain —. Chapman	602
Fish-liver oils; Spinacene, a new hydrocarbon from certain —. Chapman	392
Relationship between wetting power and efficiency of sprays of nicotine sulphate and soaps from —. Smith	99
Hardened oils; Analysis of —. Normann and Hugel	658
Herring oil; Chemical composition of —. Svendsen	657
<i>Hydnocarpus alcala</i> seed oil. Brill	1193
Linseed oil; Effect of heat and oxidation on —. Friend	462
Linseed oil; Effect of various "thinners" on the drying of —. Woodmansey	1253
Linseed oil; Test for gelatinous matter in —. Gill	345
Lumbago oil. Gardner	392
Maboula panza oil. Bolton and Hewer	346
Maboula-rana oil. Bolton and Hewer	346
Malze oil; Manufacture of —. (P) Lenders and Bauer	658
Mamurana oil. Bolton and Hewer	346
Manketti nuts; Oil of — from S.W. Africa	1018
Manufacture of a fatty product from —. (P) Klein	224
Marine animal oils; Identification of hardened —. Normann and Hugel	658
Marins oil. Bolton and Hewer	346
Menhaden oil fatty acids; Composition of —. Twitchell	802
Ministry of Munitions order relating to —	478
Moeaya oil. Bolton and Hewer	346
Murumuri oil. Bolton and Hewer	346
Olive oil; Detection of arachis oil in admixture with —. Biazzo and Vigdorick	90
—. Lund	722
Olive oil; Detection of rape oil in admixture with —. Biazzo and Vigdorick	90
Olive oil; Use of — in production of woolen and worsted goods	1203
Olive and other oils; Rapid method of obtaining neutral — suitable for preparation of camphorated oil. Cordier and Lesure	722
Orange pip oil. Hewer	969
Owala oil. Bolton and Hewer	346
Oxidation of — in presence of soluble metallic catalysts. Mackey and Ingle	317
Oxidised oils; Action of solvents on —. De Waele	149
Palm oil; Catalytic bleaching of —. Ral	948
Palm oil; Colour tests for —. Gill	346
Palm oil industry; African	1017
Palm oil prices; Ministry of Munitions order relating to —	673
Palm-kernel oil; Differentiation of — from coconut oil in mixtures. Elsdon	1103
Palm-kernel oil; Methyl nonyl ketone from —. Salway	1184
<i>Pangium edule</i> seeds; Oil from —. Brill	1193
Paraguay palm oil. Bolton and Hewer	346
Paroaxy oil. Bolton and Hewer	346
Patana oil. Bolton and Hewer	346
Perilla oil. Gardner	392
Perilla oil in Japan	723

Oils, Fatty—cont.	PAGE
Piririma oil. Bolton and Hewer	346
Rape oil; Detection of — in admixture with olive oil. Biazzo and Vigdorick	90
Rape oil; Identification of hardened —. Normann and Hugel	658
Sawarri nut oil. Bolton and Hewer	346
<i>Spartium junceum</i> seeds; Oil from —. Raffo	657
Sulphonated oils; Analysis of —. Hart	1139
Test for — by salting-out their soaps. Gill	345
Treatment of residues obtained in refining —. (P) Du Pont de Nemours and Co., and Stewart	557
Tucum oil. Bolton and Hewer	346
Tung oil in Japan	723
Tung oil in linoleum cements. De Waele	150
Turkey-red oil products; Technical analysis of —. Goldberg and Zipper	1184
Turkey-red oils; Biological valuation of —. Robert and Gruel	91
Twitchell's work on hydrolysis of —	179
Uebuba oil. Bolton and Hewer	346
Vegetable oils; Influence of climatic conditions on composition of —. Pigulevski	295
Vulcanised oils; Preparation of solutions of — obtained by the action of sulphur chloride in amyl acetate. (P) Poto	151
Whale blubber oil; Extracting —. (P) Myrens Verksed	147
Whale oil; Chemical composition of hardened —. Svendsen	603
Whale oil industry; The modern —. Munsbjerg	362
Whale oil; Ministry of Munitions notice relating to sale and purchase of —	478
<i>Ximenia americana</i> oil	1200
Zaurpruin oil	1200
Oils, Hydrocarbon:	
Action of sulphur monochloride on —. Meigs	920
Apparatus for dehydrating —. (P) Dyer	498
Apparatus for treating —. (P) Rowsey, and Illinois Refining Machinery Co.	999
Apparatus for treating heavy —. (P) Brown and De Dampierre	588r
Apparatus for treatment of natural — and their residues. (P) Barnickel	637
Aromatic base oil; Cracking of an —. The temperature factor at constant rate under pressure. Egloff and Moore	126
Crude oil; Treatment of —. (P) Barnickel	637
Dehydrating and refining —. (P) Dyer	126
Gas-oils; Cracking of — in various atmospheres. Downing and Pohlman	125
Manufacture of non-saponifiable, unsaturated — from drying oils. (P) Brooks and others	558
Mineral lubricating oils; Testing the emulsification of —. Conradson	332
Mineral oils; Continuous distillation of —. (P) Bormann	498
Mineral oils; Continuous stills for —. (P) Moore and Day	499
Mineral oils; Converting heavier — into lighter oils. (P) Lamplough	25
Mineral oils; Converting highly viscous mineral oils or highly viscous residues from distillation of — into hydrocarbons of less viscosity. (P) Rosenberg	1125
Mineral oils; Converting — into terpenes and aromatic hydrocarbons. (P) Ramage, and Bostaph Engineering Co.	637
Mineral oils; Exports of — from United States in 1916	284
Mineral oils; Oxidation of — by air. Brooks and Humphrey	997
Mineral oils; Process for obtaining from — products soluble in water or forming with it colloidal solutions. (P) Petroff	893r
Mineral oils; Process of treating —. (P) Petroff, and Twitchell Process Co.	957r
Mineral oils; Process for treating waste liquors from refining of —. (P) Wright and others	1000
Mineral oils and residues; Treatment of — to produce lower-boiling hydrocarbons. (P) White	637r
Mineral oils; Solidifying emulsion products from —. (P) Berend	26r
Mineral oils; Treating — to increase the yield of light gravity oils. (P) Day	541
Mineral oils; Treatment of — to remove sulphur, etc. (P) Lucas and others	999
Obtaining light — from heavier hydrocarbons. (P) Jenkins, and Jenkins Petroleum Process Co.	704
Paraffin oil; Solidifying —. (P) Minuto and Porte Purifying	1267
Treatment of —. (P) Snelling and Milliken	380
Electric and Manufacturing Co.	999
Olefinic terpene derivatives; Hydrogenising —. (P) Paal	163r
Oleic acid; Action of anhydrous aluminium chloride on —. Gangloff and Henderson	956
esters and their hydrogenation products. Ellis and Rabinovitz	39

Irreversible adsorption of "carbonaceous substances" of —. Rakuzin	284
Manufacture of fusel oil or similar products from —. (P) Hibbert and others	403
Manufacture of a non-volatile, unsaturated hydrocarbon from —. (P) Brooks and others	558
Nature and origin of —. Richardson	204
Obtaining products from — by decomposition of component hydrocarbons. (P) Chamberlain, and Standard Oil Co. of New York	541
oils; Apparatus for dehydrating —. (P) Prutzman	1090
oils; Process of cracking —. (P) Wells, and Ellis-Foster Co.	921
oils; Production of aromatic bodies and gas from —. (P) Mann and others	332
oils; Sulphur in —. Perkin	702
oils; Tars and tar distillates as temporary substitutes for —. Moore	587
oils; Transforming heavy — into light oils. (P) Simplex Refining Co.	127
oils; Treating —: (P) Ellis	447
(P) McAfee	1000r
soaps; Determination of free alkali in —. Charitschkov	557
spirit; Inflammability of — at low temperatures. Coste	587
Substitution of gas for —	1202
Supplies Branch of the Ministry of Munitions	125
Transforming crude — into petroleum of less density. (P) Venturino	999
Treatment of —. (P) Dubbs	921
Treatment of crude —. (P) Forward	285r
Utilisation of — in preparation of benzol. Rodano ..	1091
Pharmaceutical preparations; Risks of using commercial glucose in —. Cowie	402
preparations; Solidifying liquid —. (P) Cofman-Nicoresti	668
product. (P) Rietz, and Synthetic Patents Co.	473r
products containing arsenic; Manufacture of —. (P) Callen and others	162
products; French committee to control —	983
Phenacetin; Microchemical identification of —. Tunmann	1288
Requisition of stocks of —	479
Phenanthrene; Solubility of — in various solvents. Hildebrand and others	1267
Phenazthionium salts; Limited action of fatty amines on —. Kehrman	209
p-Phenetidinomethanesulphonic acid; Action of dilute acids and water on —. Lepetit	566
Phenol-aldehyde condensation products. (P) Van Voorhout	1185
aldehyde resins; Manufacture of permanently fusible and soluble synthetic resins from non-fusible —. (P) Berend	969
Compounds of — with pyridine. Hatcher and Skirrow	1091
and cresols; Specific gravities and boiling points of mixtures of —. Fox and Barker	844, 845
Cyclic process of making —. (P) Dennis	866
Determination of — in commercial cresylic acid. Fox and Barker	842
Determination of — in crude carboic acid and tar oils. Weiss and Downs	863
and formaldehyde and the like; Manufacture of condensation products from —. (P) Tarassoff	396r
Manufacture of —. (P) Tyrer	208, 382r
Manufacture of — from cresols. (P) Terrisse	1091
Production of — by bacteria. Berthelot	469

	PAGE
Phenol—cont.	
resin compounds; Printing plates from —. Redman and others	512
and other substances; Production of —. (P) Aylsworth and others	382
See also Carboic acid.	
Phenolcarboxylic acids; Preparation of nitriles of —. Fischer and Nouri	667
Phenolic bases; Researches on —. Von Braun and Danziger	612
bodies; Production of — from wood-tar oils. (P) Hawley	1268r
condensation products; Manufacture of —: (P) Baekeland and Gotthelf	463
(P) Jones, and General Bakelite Co.	225
(P) Redman and others	1212
Phenol-p-sulphonic acid; Mercurised derivatives of —. Rupp and Herrmann	613
Phenols and aldehydes; Manufacture of hard compositions from —. (P) Tarassoff	396r
and formaldehyde, with carbohydrides, albuminous materials, and tannins; Production of hard compositions from —. (P) Tarassoff	150
and formaldehyde; Manufacture of condensation products from —: (P) Berend	347
(P) Tarassoff	1019
and formaldehyde; Manufacture of hard condensation products of —. (P) Tarassoff and Shestakoff ..	558
and formaldehyde; Manufacture of insoluble condensation products from —. (P) Reeser	1185r
formaldehyde, and salts of sulpho-acids; Preparation of solid condensation products from —. (P) Tarassoff and Shestakoff	150, 1055r
Identification of —. Reid	333
Manufacture of —. (P) Ramage, and Bostaph Engineering Co.	208
mercurised; Disinfecting power of —. Schoeller and Schranth	564
New class of mixed phthalates from p-hydroxybenzoyl-o-benzoic acid and —. Orndorff and Murray ..	542
polyhydric; Influence of the solvent on the reaction between — and alkali bicarbonates. Von Hemmelmayr	1268
Spectroscopic identification of —. Forezák and Knop	922
Phenylarsine-p-carboxylic acid, Sieburg	1027
o-Phenyl ^{2,2,7} -butadiene; Polymerisation of —. Lebedev and Ivanov	305
p-Phenylenediamine; Product of oxidation of — by hydrogen peroxide. Heiduschka and Goldstein	1002
Phenylethylene; Action of anhydrous aluminium chloride on —. Gangloff and Henderson	956
Phenylethylhydantoin, a new hypnotic and sedative. Wernecke	46
Manufacture of —. (P) Meister, Lucius, u. Brüning	615
Phenylglucosides; Synthesis of the —. Fischer and Von Mechel	303
Phenyl- α -naphthylamine; Preparation of —. Katayama	865
2-Phenylquinoline-4-carboxylic acid; Compounds of cinchona-alkaloids with —. (P) Davis	943
Philippine cacao; Fermentation of —. Brill	1245
tanbarks. Gana	1106
Philippines; Dyeing materials in the —	506
galvanised-iron roofing in the —. Argüelles	553
Phoretin; Synthesis of —. Fischer and Nouri	667
Phonolites; Substitution of finely crushed Austrian — for Stassfurt potash salts. Stoklasa	1058
Phosgene. See Carbonyl chloride.	
Phosphate; Acid —. See Superphosphate.	
fertilisers; Manufacture of —. (P) Volpato	898
material; Decomposition of raw — for manufacture of fertilisers. (P) Barth	398
rock; Determination of phosphoric acid in —. Semple	933
rock and potassium-containing silicates; Treating —. (P) Bassett, and Sjar Chemical Co.	455
rock; Production of available phosphorus from — by composting with sulphur and manure. Brown and Warner	1281
rock; Use of the Cottrell precipitator in recovering phosphoric acid evolved in the volatilisation method of treating —. Ross and others	134
Phosphates, citrate-soluble; Manufacture of —: (P) Lipman	560
(P) Newberry	152r
Constitution of the alkali —. Smith	420
Determination of — by alkalimetric methods. Smith	415
double; Some new —. Smith	420
Method of treating —. (P) Menninger	899r
mineral; Sulphur oxidation in soils and its effects on the availability of —. Lipman and others	227
Relative availability of acid phosphate and raw rock —. Conner	349
rock; Rate of reversion of mixtures of superphosphate with —. Robertson	626
Solubility of mineral — in dilute mineral and organic acids. Aita	807
Vegetation experiments on availability of treated —. Lipman and McLean	1281

compounds; Vulcanisation of —. (P) Hofer	1243
compounds for wire and cable insulation	1140
cripe; Influence of rolling on —. De Vries and Swart	1140
Degree of acidity of raw —. Van Rossem	1105
Depolymerisation and oxidation of raw —. Van Rossem	1242
Determination of free and combined sulphur in vulcanised —. Eaton and Day	16
Devulcanisation of —. (P) Spence	1055
Different methods of preparing —. Dekker	970
Drying pulverised reclaimed —. (P) Price, and Rubber Regenerating Co.	297
Effect of fungus "spot" disease development on —. Eaton	1222
from <i>Eucommia ulmoides</i> . Sievers	558
exports from Brazil	512
Further experiments on the combined sulphur content of slow and fast vulcanising plantation Para —. Eaton and Day	1116
Hevea; Comparative studies on different varieties of — from the Amazon district, Brazil. Heim ..	894
hose for use on aeroplanes. Houseman	512
Impregnating fabrics with —. (P) McGiehan	869
Indirect method of determining percentage of —. Van Rossem	1105
industry; Scientific needs of the —. Porritt	789
Influence of age of trees on quality of —. De Vries	1104
Influence of amount of acetic acid used for coagulation on quality of —. De Vries and others	1140
Influence of rubber content of latex on quality of —. De Vries	1104
Insulating article composed partly of —. (P) Kennington, and Remy Electric Co.	462
Insulation Committee; Report of joint —	464
Kneading machinery for —. (P) Davidson	397
latex; Bacteriological study of natural coagulation of —. Denier and Vernet	970
latex; Coagulating —:	
(P) Ilcken and Down	1280
(P) Thomas and Maude	465
latex; Determination of percentage of caoutchouc in —	931
latex; Natural coagulation of <i>Hevea</i> —. Campbell	274
latex; Non-caoutchouc compounds of —. Dekker	970
latex; Partial coagulation of —. De Vries	1104
in the latex; State of colloidal aggregation of —. Van Heurn	970
Machine for washing and disintegrating raw — and materials containing it. (P) United Engineers, Ltd.	3967
Manufacture of a filler for —. (P) Rosevear	1140
Manufacture of plastic material from —. (P) Peachey	10197
Organic accelerators of vulcanisation of —. Peachey and paper yarn; Manufacture of heat-resistant goods from —. (P) Kramer	895
Para; Natural vulcanisation accelerator of —:	
Eaton	1224
Stevens	365
Percentage of moisture in raw —. Van Rossem	1104
Percentage of resin, mineral matter, and nitrogen in —	1055
Permanent set of —. De Vries and Hellendoorn ..	1258
plant, rich in rubber, indigenous to Germany. Schiller ..	727
plantation; Investigations of quality of — conducted under Ceylon rubber research scheme	604
plantation Para; New researches on variability of —. Eaton	1217
plantation Para; Rate of combination of sulphur with different types of —. Eaton and Day	16
plantation Para; Variability of —. Whitby	444
products; Determination of mineral matter in —. Péregin	347
Relation of vulcanisation coefficient to physical properties of —. Eaton and Day	1118
Relationship of mechanical to chemical properties of vulcanised —. Spence	92
Removing combined sulphur from vulcanised —. (P) Spence	1056
Roller apparatus for treatment of —. (P) Hodgins ..	5127
Separating — from fabrics of used pneumatic tyres. (P) Debaug	1019
So-called insoluble part of raw —. Van Rossem and Dekker	1105
solutions; Viscosity of —. Van Rossem	1104
substitutes. (P) Flint	1019
substitutes; Manufacture of vulcanisable elastic masses for use as —. (P) Ali-Cohen	1140
substitutes and paper yarn; Manufacture of heat-resistant goods from —. (P) Kramer	895
Sugar as coagulant for —. De Vries	604
Tackiness in raw —. Gorter	604
Treating —. (P) Hunter, and Hunter Dry Kiln Co.	465

Rubber— <i>cont.</i>	
Treatment of vulcanised —: (P) O'Neill and others ..	12437
Vulcanisation of —:	
(P) Bernstein	11057
Dubose	236
(P) Dunlop Rubber Co., and Twiss	1185
(P) Hofer	1243
(P) Ostermislensky, and New York Belting and Packing Co.	1243
(P) Price, and Rubber Regenerating Co.	1149
(P) Randall, and Boston Rubber Shoe Co.	347
vulcanisation accelerators; Organic —. Spence ..	118
Vulcanisation of — by agents other than sulphur.	
Stevens	107
vulcanisation catalysts:	
Peachey	959
Twiss	1072
vulcanisation; Chemistry of —. Twiss	782
vulcanisation; The most practical accelerator of —.	
Hutin	1140
vulcanisation tests. Campbell	92, 1280
waste; Process of recovering —:	
(P) Kinsley and others	396
(P) Mechanical Rubber Co.	12437
Water extract of raw —. Van Rossem	1103
Wet combustion in the nitrosite combustion method for direct determination of —. Wesson and Knorr ..	347
See also India-rubber.	
Rubbers; Vulcanisation results obtained with — from seven plantations. Schildrowitz and Goldsbrough ..	971
Rum distillery; Scientific control of a —. Seard	157
Manufacture of colonial —. (P) Hervé	158
Rumex; Identification of —. Beal and Okey	595
Rust-proofing iron and steel. (P) Allen, and Parker Rust Proof Co. of America	597
-proofing metals. (P) Allen, and Parker Rust Proof Co. of America	222, 460
-proofing metals; Tanks for —. (P) Parker	968
Removal of — from iron plates. Watson	341
Ruthenium; Action of oxygen on —. Gutbier and others ..	222

S.

Sabinols; Isomeric —. Paolini and Rebora	352
Saccharate waste waters; Treatment of —. (P) Monroe, and Dyer Co.	1059
Saccharifying amylaceous substances. (P) Beklin and Elfront	7327
distillers' mashes by means of malt. Vasseux	1284
raw cereal mashes in brewing. Thevenot	900
Saccharin; Determination of — in foods. Gnadinger ..	976
Saccharophosphatase of yeasts, and the fermentation of sucrose-phosphoric acid. Djenab and Neuberg ..	1284
Saccharose. See Sucrose.	
Sacks; Waterproofing paper-yarn —. Cassella und Co.	592
Saggars. (P) Aynsley and Reynolds	648
St. Domingo; Presence of invertase in cane sugar from —. Pellet	152
Sajji mitti; Utilisation of — for manufacture of commercial alkalis. Silver	1006
Salford; Activated sludge sewage purification plant at —. Ardern	824
Salicylic acid; Application of Daclaux's method to detection of — in presence of salicylic acid. Richmond ..	520
Manufacture of —. (P) Everett and Co., and others ..	614
Microchemical identification of —. Tunnmann ..	1288
Preparation of — by electrolytic oxidation of <i>o</i> -cresol. (P) Pomilio	382
vapour; Condensation of —. (P) Pugh	907
Salin de Giroud; Bromine and potassium salts industry at —. Manzella	641
Saline solutions; Separation of calcium and magnesium in —. (P) Glaser	1235
Salt-brine; Process for purifying —. (P) Hartsuch, and Buckley and Douglas Lumber Co.	1008
manufacture by solar evaporation of sea water. Palmer ..	502
Recovery of — from its admixture with impurities in crude brine. (P) Skinner and Baughman	1271
Removal of barium chloride from brines used in the manufacture of —. Skinner and Baughman ..	134
sea-; Potassium chloride from mother-liquors in manufacture of —. Fishimura	1046
works; Utilisation of mother liquors from marine — as a source of potassium salts. Manzella	453, 641
See also Sodium chloride.	
Salt-cake in the glass industry. Springer	873
Use of nitre cake in manufacture of —. Grisley	1216
See also Sodium sulphate.	
Salt-petre. See Potassium nitrate.	
Chile —. See Sodium nitrate.

Salts; Eliminating and recovering — from vulcanised fibre. (P) Tiffany, and Continental Fibre Co.	708
Influence of — on bacterial activities of soils. Greaves	227
Mechanism of absorption of — in plants. Pantanelli	41
Purification of — by "clairceage" or by fractional crystallisation. Rengade	961
Recovering — from mixtures in solution. (P) Trump, and Solvay Process Co.	456
Separating — from solutions. (P) Newby and Montgomery	23r
Sambunigrin; Synthesis of — and of similar substances. Fischer and Bergmann	1288
Sampling device for pulp digesters. (P) Tuttle	544r
Sand; Apparatus for drying —. (P) Bratton, and Pennsylvania Glass Sand Co.	633
-blasting; Cleaning metals by —. Scott	813
Dryers for —. (P) Dance, and Dyar Supply Co.	858
Fusions from exploding gun-cotton. Munroe	669
glass; Determination of iron in —. Ferguson	1235
-lime bricks; Manufacture of —. (P) Charlton	1010
-lime bricks; Silica bond in —. Emley and others	880
-lime bricks; Specific heat of —. Kinoshita	597
Machines for washing —. (P) Southall	1263
for mortar; Colorimetric determination of organic impurities in —. Abrams and Harder	718
washer for washing fine sand. (P) Southall	494
Sandarac; Detection of — in resins, lacs, and partially manufactured materials. Sacher	894
Sands, glass; British —; their location and characteristics. Boswell	216
glass; Substitution of British for foreign — for high-grade glass making. Peddle	216
used in metallurgical practice and in glass manufacture. Boswell	753
Sanitary ware; Fritted leadless glazes for —. Parmelee and Williams	717
Santene; Complete synthesis of —. Komppa and Hiltikka	304
Saponin; Determination of active oxygen in detergents containing —. Grün and Jungmann	658
in extracted beetroot. Andrik	560
from <i>Pucca filamentosa</i> . Chernoff and others	234
Sappan (<i>Cassipouia sappan</i>) in the Philippines	706
Saurol, a substitute for ichthyol. Méran	162
Sawarri nut oil. See under Oils, Fatty.	
Sawdust; Briquetting —. (P) Behr	285
Use of — for gas making	1123
Scheelite production in New Zealand	36
Production of tungsten from —. (P) Butterfield and Ashworth	461r
Scientific Societies; Conjoint Board of —	632
Scopolamine; Detection of —. Eder	941
Scottish shale industry; Appointment of committees on —	282
Scouring wool and other fibrous materials; Machines for —. (P) Whitaker	1045
Screens for moving and other projected pictures. (P) Meadow, and British Patent Subrite Co.	403
Scrubbers; Valves for controlling, reversing, and by-passing the flow of the gas through —. (P) Dempster and Sons, and Horsfall	1264r
Scrubbing of gases; Intensive —. Blauvelt	125
towers; Packing or filling for —. (P) Oates and Robinson	1170
Sea mammals; Making meat of — fit for food. (P) Holzapfel	610
Sealing glass bulbs containing a gas in solution. (P) Loepfinger, and General Fire Extinguisher Co.	1177
wax. (P) Snelling	1130
Seaweed; Dyeing with —. (P) Malcolmson and Kelsey	960
Extraction of iodine from green —. (P) Vincent	137
as feeding stuff. Kling	1060
Japanese —. Miyama	135
Secreting. See Carotol.	
Sedative; A new — phenylethylhydantoin. Wernecke	46
Sedoheptose, a new sugar from <i>Sedum spectabile</i> . La Forge and Hudson	731
<i>Sedum spectabile</i> ; Sedoheptose, a new sugar from —. La Forge and Hudson	731
Seeds; Action of illuminating gas on germination of —. Wehmer	1021
Apparatus for cooling and drying — in bulk. (P) Schuler	98
Apparatus for drying —. (P) Hewett	858
Apparatus for expressing oil or other liquid from —. (P) Barton	1054
Effects of salt-treated soils on absorption by —. Gerike	607
Fertilisers for —. (P) Barberi	1244
Machines for expressing oils or liquids from —. (P) Schuler	1054
Ministry of Munitions order relating to dealings in —	523
Restricted dealings in —	523
Treatment of —. (P) Fry and De Wolf	467r
Treatment of growing —. (P) Grünberg	229
Treatment of — before sowing. (P) De Wolf and Fry	41

Selenic acid; Reduction of —. Benger	1233
Selenium and like sensitive cells. (P) Martinez	1183
toning bath for photographic silver prints. (P) Schering	615
Selenophthalene and their halogen derivatives; Manufacture of —. (P) Meister, Luchs, u. Brüning	211
Semicarbazide; Estimation of — by interaction with halogens and halogen oxyacids. Datta and Choudhury	46
Semi-fluid substances; Extracting fluid from —. (P) Hood	1261r
Sendoxamizide; Estimation of — by interaction with halogens and halogen oxyacids. Datta and Choudhury	46
Senna; Identification of —. Beal and Okey	565
Identification of — in medicinal preparations. Hubbard	667
Separating adsorbed, colloidal, soluble, or finely-divided substances from substances carrying them. (P) Elektro-Osmose A.-G.	202
air or other gaseous fluid from liquids. (P) Walker ..	917
certain constituents from a gas or mixture of gases. (P) Bradley and others	538
component parts of liquids. (P) Sheehan and McCay ..	202
the constituents of gaseous mixtures. (P) Claude, and Soc. l'Air Liquide	330r
the constituents of liquids. (P) Schmidt and others ..	917
constituents of or materials suspended in gaseous bodies; Electrical method and apparatus for —. (P) Schmidt	1102r
finely-divided substances from coarse and foreign matters. (P) Schwerin, and Elektro-Osmose A.-G.	860r
foreign bodies from pasty masses prior to drying. (P) Jung	700
Immiscible liquids; Apparatus for —. (P) Sands and Gourlay	698
Impurities from liquids by centrifugal force. (P) Hamill ..	633
liquids from gases; Apparatus for —. (P) British Thomson-Houston Co., and others	1228
liquids from solids in fluid suspension; Apparatus for (P) Blomfield	1228r
(P) Blomfield and The Dorr Co.	1088
liquids from solids; Continuous process for —. (P) Behr	1171
material from one liquid by another; Continuous process for —. (P) Hansbrand	699
miscible liquids from one another. (P) Newby and Montgomery	23r
and purifying finely-divided substances. (P) Schwerin, and ties, für Elektro-Osmose	860r
salts from solutions. (P) Newby and Montgomery	23r
solids by centrifugal force. (P) Sharples	124r
solids from fluids, or fluids from fluids; Apparatus for —. (P) Moss	1122r
(P) Moss and Smith	1068
solids from liquids; (P) Herr	375
(P) Sharples	917
solids from liquids; Apparatus for —. (P) Russell, and Dorr Co.	330r
substances of different specific gravities; Apparatus for —. (P) Draper	124r
substances; Magnetic or inductive process of —. (P) Osmond	390
unfilterable material from a mixture of filterable and unfilterable matter. (P) Merrill	634r
uniform or mixed materials according to density or size of particles; Apparatus for —. (P) Bernard and Vihert	124
vapour from gas and other fluids; Apparatus for —. (P) Frohlich	585
water and other impurities from oil. (P) Sands	23r
Separators and amalgamators; Centrifugal —. (P) Zimmer	510
Centrifugal —: (P) Brown	74
(P) Parker	996
(P) Spelman	375
Centrifugal — for liquids. (P) Reece	918
Centrifugal — and methods of working them. (P) Gee ..	858
Centrifugal — for removing tar and oils from wood distillation vapours. (P) French	333r
Centrifugal self-balancing —. (P) Riggs	1227
Electromagnetic —. (P) Hallimond and Fletcher ..	1182
Electrostatic — for inflammable materials. (P) Kraus ..	538r
for grinding mills. (P) Price	585
Magnetic —: (P) Davies, and Allen and Co.	600
(P) Hardy Patent Pick Co., and Smith	1136
(P) Jones	955
(P) Krupp A.-G. Grusonwerk	600
Septic tank. (P) Ferguson	665
Sera, antitoxic; Influence of the reaction of — in their concentration. Homer	734
Serichn; Degradation of — by ozone. Harries and others ..	567
Serum, antidiathermic; Selective adsorption of — by aluminium hydroxide. Rakuzin and Flier	735
Serums; Optical activity of —. Rakuzin	732

Sewage; Apparatus for aerating —. (P) Ames 519, 977, 1247	
Apparatus for treating —. (P) Irwin, and Anglo-Continental Fertilizers Synd., Ltd. 519r	
containing organic matter; Electrolytic purification of —. (P) Ter Meer and Reubold 519	
creamery; Removal of casein and albumin from —. (P) Ebrill and Kiersey 160	
(P) Ebrill and others 904r	
Determination of nitrates in — by means of <i>o</i> -toluidine Phelps and Shoub 1026	
Disposal of — by means of micro-organisms. (P) Starr and Robinson 611	
disposal; Method of —. (P) Potter 161	
Interaction of chloride of lime with normal constituents of —. Heise 1191	
Means for treating —. (P) Noble 303	
Production of hydraulic lime and cement from combustion residue of —. (P) Elsner 504r	
Purification of —:	
(P) Janvier 303r	
(P) Jones, and Jones and Attwood 471	
purification; Activated sludge process of —. Ardern 65	
purification; Activated sludge process of — at Worcester, Caikn 938	
Purification of — by aeration in presence of activated sludge, Bartow 1146	
purification; Experiments relating to the activated sludge process of —. Lockett 264	
purification; Present position of activated sludge process of —. Ardern 822	
Recovery of fat and nitrogen compounds from —. Rideal 44	
sludge; Apparatus for drying and treating —. (P) Annison 329	
sludge; Manufacture of fertilisers from —. (P) Furze 1143	
sludge; Expressing liquid from —. (P) Hinchley and Gorton 1263	
sludge; Practicability of recovery of nitrogen in —. Copeland 517	
Tanks for purification of —. (P) Caikn 611	
Tanks for treatment of —. (P) Scarborough 611	
Treatment of —:	
(P) Menzies 905, 905r	
(P) Sawyer 1287	
Treatment and purification of —. (P) Martin 160	
water; Apparatus for purifying —. (P) Bredlin 233	
Shaft-furnaces; Electrically heated — for recovering metals from low-grade ores and slags. (P) Westdeutsche Thomasphosphat-Werke 601	
kilns; Preventing admission of "false air" into —. (P) Polysius 597	
Shakudo. Miyasawa 884	
Shale; Distillation of —. (P) Heyl 381	
distillation products; Apparatus for the continuous fractionation and dephlegmation of —. (P) Allan 127	
Electrical conductivity of — upon heating. Kinnison 876	
Extracting volatiles from —. (P) Bussey 958	
fireclay, and surface clay; Study of mixtures of — with reference to their porosity-temperature relations. Brown 876	
Industry; Appointment of committees on Scottish —. Manufacture of combustible fluids from —. (P) Reid, and Patents Process Co. 637	
Shales; The Norfolk oil —. Forbes-Leslie 204	
Sheep dips. (P) Lemmens and Fryer 303, 611, 734, 1247r, 1247r	
Shellac derivatives; Inhibition exhibited by some —. Laurie and Ranken 1241	
substitute; Manufacture of — from paraffin hydrocarbons. (P) Zerning 541	
Shells; Explosive charge for —. (P) Stern 101	
Sherungulu tubers; Essential oil of — 100	
Shibuchi. Miyasawa 884	
Ships; Ferro-concrete — 492	
Shortening composition for dough; Manufacture of a —. (P) Kolman and others 1286	
Shrewsbury-Knapp and Reichert-Polenske process for determining coconut oil; Combined modified —. Eidsen 1103	
Siberia; Zinc-lead smelting plant at Ekibastus — 342	
Sibucan. See Sappan.	
Sicilian sulphur; Supplies of — 523	
<i>Sida rhombifolia</i> fibre 1003	
Siegerland spiegelstein blast-furnace; Investigation of the —. Thaler 598	
Silage; Alfalfa —. Swanson and Tague 1060	
Bacteriology of —. Sherman 1144	
fermentation; Micro-organisms and heat production in —. Hunter 1060	
Occurrence of <i>L-leucine</i> in sweet clover —. Plaisance 1145	
Occurrence and significance of mannitol in —. Dox and Plaisance 1145	
Relative influence of micro-organisms and plant enzymes in the fermentation of maize —. Lamb 470	

	PAGE
Silica; Accurate determination of — in commercial analysis. Hawley 521	
brick mixtures; Volume-changes of —. Heiminger and Ross 718	
bricks. Le Chatelier 964	
bricks; Manufacture of —. Nesbitt and Bell 1049	
bricks and some new uses for them. Gray 387	
bricks for steel furnaces from the consumer's point of view. Brooke 1273	
and carbon dioxide; Equilibrium between — in alkali, lime-alkali, and alkali aluminate fusions. Niggli 643	
Fused —. Bottomley 577	
hydrogels; Behaviour of — at low temperatures. Vanzetti 595	
potash, lime, and alumina; Study of the most fusible mixtures of —. Hanna 877	
-potassium metasilicate-water; The ternary system —. Morey and Fenner 871	
Process for fusing —. (P) Rosenblum 879	
Production of white — for finishing paper, textiles, etc. (P) Varcoe 712	
Reactivity of — with oxides of calcium, barium, and magnesium in the solid state. Hedvall 643	
Refractory properties of —. Le Chatelier and Bogitch 963	
-soda-zinc oxide; Microscopic investigation of some compounds noted in the system —. Klein and Brown 878	
-soda-zinc oxide-titanic oxide; Microscopic investigation of some compounds noted in the system —. Klein and Brown 878	
vessels; New acid sodium phosphate and its action on —. Smith 419	
Silicate-glasses; Treatment of — and preparation of soluble silicates therefrom. (P) Spensley and others 1007	
rocks; Extraction of potash from —. Ross 642	
Silicates, base-exchanging; Manufacture of —. (P) Kriegsheim, and Permutit Co. 215, 503r	
Manufacture of aluminium salts from —. (P) McKee 646	
Manufacture of fertilisers from —. (P) Jackson and Horney 1021	
Manufacture of magnesium compounds from —. (P) Peacock, and Marden, Orth, and Hastings Co. 925	
Manufacture of soluble — from silicate glasses. (P) Spensley and others 1007	
Obtaining alkali metal compounds from —:	
(P) Schmidt 1094	
(P) Schmidt, and International Precipitation Co. and phosphate rock; Treating potassium-containing —. (P) Bassett, and Spar Chemical Co. 455	
Process of decomposing —:	
(P) Charlton, and Kaolin Products Corporation .. 1008	
(P) Jackson and Horney 1008	
Recovery of potassium and aluminium salts from mineral —. Frazer and others 1234	
Titration of calcium oxide or hydroxide in presence of some —. Emley 871	
Treatment of —. (P) Cowles 962	
Silicon-coated metal. Vawter 885	
Obtaining — from clay. (P) Weaver Co. 144	
Process for securing — from its compounds. (P) Weaver, and Weaver Co. 1235	
and its thermo-electric power. Fischer and Baerwind .. 502	
Silicon carbide and ferro-silicon; Deoxidation of iron and steel alloys by —. (P) Trenheit 928	
carbide refractory articles. (P) Tone 718r	
compounds for water softening; Manufacture of —. (P) Boehringer, and Staten Island Chemical Corporation 83	
fluoride; Manufacture of hydrofluoric acid from —. (P) Chappell 1271	
Silk, artificial; Apparatus for treating threads of —:	
(P) De Chardonnet 1232r	
(P) Linfoot, and Courtaulds, Ltd. 870r	
artificial; Apparatus used in the manufacture of —. (P) Clayton, and Courtaulds, Ltd. 1126	
artificial; Funnels or thread guides for machines for manufacture of —. (P) Courtaulds, Ltd., and Clayton 593, 593r	
artificial; Machine for spinning —. (P) De Chardonnet 132r	
artificial; Manufacture of —:	
(P) Kishi 870r	
Wilson 817	
artificial; Manufacture of — from esparto. (P) Trigos 131	
artificial; Process for obtaining threads, etc., of —. (P) Leduc and Jacquemin 335r	
fibres; Process for treating —. (P) Kanegafuchi Boseki Kabushiki Kaisha 959	
filaments and fabrics; Apparatus for weighting — in the form of hanks. (P) Schmid 924	
Fixing iron mordants on —. (P) Gebr. Schmid 80	
Increasing the lustre of — in hanks and woven goods. (P) Reidenmeister 213	
raw; Specific heat of —. Kinoshita 597	
Treatment of weighted — to increase its strength and elasticity. (P) Schadd and Korteling 133	
Weighting of —:

Titanic products; Manufacture of —. (P) Titanium Alloy Manufacturing Co.	647r	Transfers for earthenware, china, glass, and enamelled goods	
sulphate products; Manufacture of basic — and pure titanate oxide therefrom. (P) Barton, and Titanium Alloy Manufacturing Co.	659	Production of —. (P) Brindley.	85
Titaniferous iron ores; Electric smelting of —. Stansfield iron ores; Reduction of —. (P) Loke.	881	Transportation of grain and granular materials; Vacuum pumps or compressors used for pneumatic —. (P) Bentham, and Simon, Ltd.	1263
Titanium ores; Distribution and uses of —.	1012	of liquids:	
Preparation of pure —. Podzus.	1012	Baxter.	1226
Production of alloys of — with tungsten, molybdenum, tantalum, etc. (P) Podzus.	929	Eisenhart.	1226
in Taranaki iron sand. Donovan and others.	292	and storage of liquids in small packages. Adkins.	1226
Titanium dioxide and carbon dioxide; Equilibrium between — in alkali, lime-alkali, and alkali aluminate fusions. Niggl.	643	Trans; Production of metal coatings on —. (P) Sanders	33r
oxide; Manufacture of —. (P) Barton, and Titanium Alloy Manufacturing Co.	84, 84, 84, 1047	Treasurer; Statement of honorary —.	746
-oxygen compounds; Manufacture of —. (P) Norske Aktieselskab for Elektrochem. Ind. Norsk Industri-Hypotekbank.	1272	Treating metals and other materials by heat; Method of —. (P) De Bats and others.	391
Titration; Apparatus for electrometric — depending on the change of oxidation potential. Kelley and others.	1011	Triarylmethane dyestuffs fast to light; Manufacture of —. (P) Meister, Lucius, u. Brünig.	287
In stages by means of two indicators. Reichard.	399	Triarylmethane; dyestuffs; Manufacture of leuco — and of their copper compounds. (P) Soc. Chem. Ind. in Basle.	1002
Tobacco; Dehydrating and curing —. (P) Benjamin	668, 1065	dyestuffs; Manufacture of leuco — and of their metal compounds and their application in dyeing. (P) Soc. of Chem. Ind. in Basle.	1002
Determination of nicotine in —. Tingle and Ferguson leaves; Examination of methods of estimating nitrogenous substances in —. Paris.	666	Tribromo-tertiary-butyl alcohol; Acetic ester of —. Aldrich and Beckwith.	100
-plant beds; Sterilizing soil for —. (P) Young and Chapman.	560	Triclinium aluminate; Formation of — in Portland cement. Campbell.	1236
plants; Process for treating the green juice of —. (P) Oelenbein.	163r	Tridymite; Conditions of stability of —. Le Chatelier.	964
smoke; Removal of nicotine from —. Tóth and Dingelmaier.	160	Formation of — in siliceous bricks. Le Chatelier.	964
o-Tolidine; Determination of nitrates in sewage by means of —. Phelps and Shoub.	1026	Trihalogen-tertiary-butyl alcohols; Derivatives of —. Aldrich and Beckwith.	100
Toluene; Action of — on fermentation processes. Buchner and Skraup.	1189	Trimethylglucose from cellulose. Denham and Woodhouse	607
Analysis of light oils for benzene, xylene, and —. Eglhoff.	498	s-Trinitrobenzene; Additive compounds of —. Sudborough.	128
Determination of — in coal tar oils. Barker.	590	Additive compounds of — with amino-derivatives of complex aromatic hydrocarbons. Cadre and Sudborough.	128
Determination of — in crude benzols. Spielmann and Petrie.	832	Preparation and properties of —. Radcliffe and Pollitt.	269r
Electrochemical chlorination of —. Fichter and Glantzstein.	207	Trinitro-tert-butyltoluene; Preparation of —. Kikokoro	1065
extraction from coal gas. Applebee.	635	Trinitrophenylmethylnitramine. Van Duhn.	1030
Heat of combustion of —. Richards and Davis.	474	Trinitrotoluene; Inspection and testing of —. Stevens.	1029
Oil washing for recovery of — from coal-gas. Adam from petroleum. Bender.	582	Manufacture of —. (P) Quartieri.	1149r
Preparation of nitro-derivatives of —. Kikokoro.	1065	Order-in-Council relating to —.	947
Production of —. (P) Sifton.	382r	Preparation of —. Kikokoro.	1065
Products of the action of heat on —. Meyer and Hofmann.	865	U.S. Navy Department specifications for —.	164
Proposed manufacture of — in Australia.	705	Triphenylmethane dyes;	
Sources of — for high explosives. Rhead.	764	Brilliant Green as an antiseptic. Browning and others	161
See also Toluol.		Effect of additional auxochromes on colour of —. Ghosh and Watson.	1126
Toluol in coal-gas; Apparatus for determination of —. Copp.	378	Manufacture of —:	
Gas washing for —; analysis of products; control of stills. Edwards.	539	(P) Meister, Lucius, u. Brünig.	449
containing paraffins; Nitration of —. (P) Fluerschheim, and Actina Explosives Co.	670	(P) Schmidlin and Fischer.	500
Manufacture of —:		Manufacture of blue —. (P) Weller, and Synthetic Patents Co.	419r
(P) Evans, and United Gas Improvement Co.	866	Trisazo dyestuffs. See under Azo dyestuffs.	
(P) Gartley.	1231r	Tröstite; Formation of —. Dejean.	965
(P) Gartley, and United Gas Improvement Co.	638	Tropaeoline; Tests for —. Hankin.	565
Production of — from heavy oils. (P) Anderson and Meikle.	1001	Tropinone; Synthesis of —. Robinson.	1062
Recovery of — in gas-works.	1265	Trypalanine. See Flavine under Acridine dyestuffs.	
See also Toluene.		Trypsin; Yeast —. Dornby.	1023
o-Tolylhydrazine as a sensitive reagent for <i>D</i> -galactose. Van der Haar.	1022	Tryptic digestion; Optimum reaction of —. Long and Hall.	732
p-Tolylhydrazones of <i>L</i> -arabinose, rhamnose, fucose, <i>D</i> -mannose, and <i>D</i> -galactose. Van der Haar.	662	enzymes; Stabilising —. (P) Riebensahn.	605
Tool-steel alloys. (P) Furness and others.	142	Tube-mills. (P) Marcy.	699
Tools; Use of high-speed cast steel.	1276	-mills; Grinding in —. (P) Schultz, and Smith and Co.	633
Tow; Manufacture of — from esparto. (P) Trigos.	131	-mills; Limer for —. (P) Johnson, and American Manganese Steel Co.	1263
Towers; Packing or filling for absorption, recovery, or scrubbing —. (P) Gates and Robinson.	1170	<i>Tubera salep</i> extract as protective colloid. Gutbier and Kräutle.	943
Toxicity of various benzene derivatives to insects. Moore.	939	Tuberculin; Adsorption of Koch's — by aluminium hydroxide. Rakuzin and Flier.	305
Toxins; Adsorption of — by aluminium hydroxide. Rakuzin and Flier.	305	Selective adsorption of Dony's — by aluminium hydroxide. Rakuzin and Flier.	734
Manufacture of — by oxidising ferments. (P) Boldin and Elfront.	732r	Tubers; Preparing — for manufacture of dough or flour for bread or bakers' wares. (P) Simons.	733
Optical activity of —. Rakuzin.	732	Tubes, paper; Experiments with —. Rudeloff.	592
plant; Soil constituents which inhibit the action of —. Truog and Sykora.	659	Refractory-metal —. (P) Coolidge, and General Electric Co.	656r, 722
Trade after the war; Financial facilities for — especially in relation to raw materials and conversion of works during and after the war; report of committee of London Chamber of Commerce.	21	Tubular fabrics; Device for drying —. (P) Cohn.	23
marks; Interests of British and enemy subjects in —.	407	Tucum oil. See under Oils, Fatty.	
Trades of primary importance; List of —.	308	Tung oil. See under Oils, Fatty.	
Transference of heat between liquids and vapours of gases; Devices for —. (P) Sawyer and Hiltson.	581	Tungstates of cobalt-ammonium compounds; Use of — in determination of cobalt. Carnot.	908
of loose material; Method and means for —. (P) Blyth and Lister-Kaye.	535	Tungsten alloys; Manufacture of high-percentage —. (P) Goldschmidt and others.	1016r
		coated with gold or gold-palladium alloy. (P) Fahrenwald.	889
		Coating — with noble metals. (P) Fahrenwald.	1016
		crystals; Manufacture of all-form — for incandescence electric lamps. Pöttger.	511
		electric resistance tube. (P) Coolidge, and General Electric Co.	722

liquors from refining of mineral oils; Process for treating —. (P) Wright and others 1000	
lyes from cellulose manufacture; Manufacture of artificial graphite from —. (P) Messow 873	
manufacturing; Means for treating liquid —. (P) Noble 303	
materials; Lead-bearing — as ingredients of glazes. Miller 878	
mine-; Utilisation of — by means of the heat of waste fields. (P) Ostwald 956	
oils from motor garages; Utilisation of —. (P) Heyl 1266	
products of breweries; Manufacture of neutral non-drying adhesives from —. (P) Kühle 895	
products of coal and other fuels; Conversion of — into inflammable gas for consuming smoke in furnaces. (P) Shill and others 861	
sulphite pulp liquor; Utilisation of —. (P) Fest 451	

Water; Absorption of atmospheric gases by —. Coste 846	
analysis; Contributions to —. Winkler 685	
analysis; Titration of magnesium in —. Bruck-müller 563	
Apparatus for adding chemical reagents to —. (P) Paterson 611	
Apparatus for cooling —. (P) Thomas 698	
Apparatus for decarbonating — especially for brewing. (P) Werle 733	
Apparatus for distilling and evaporating —. (P) Forbes 940	
Apparatus for electrolytic decomposition of —. (P) Dolman 295	
Apparatus for heating —: (P) Ajax Heaters, Ltd., and Russell 1086	
(P) Hocking 1171	
Apparatus for softening —. (P) Künzlg, and Opten-berg Iron Works 564	
Apparatus for treating —. (P) Ornstein, and Electro Bleaching Gas Co. 978r	
Application of thymolphthalein and naphtholphthalein in determination of true neutrality in —. Moir 571	
boiler feed-; Combined evaporator and heating apparatus for — for power plant. (P) Griseoni-Russell Co., and Jones 1227	
boiler feed-; Determination of sodium and calcium bicarbonates in —. Mouthaupt 160	
boiler-; Process of treating —. (P) Kriegsheim, and Permutit Co. 1062	
boiler-; Purifying —. (P) Kriegsheim, and Permutit Co. 1287	
for brewing; Eliminating carbonate hardness of —. (P) Hess 936	
Cleansing filtering material in apparatus for softening and purification of —. (P) Lassen and Hjort 905	
content of coal. Mack and Hulett 378	
cooling towers. (P) Evans 376	
cooling towers; Water-distributing arrangement for —. (P) Dansk Jernbetonkonstruktions Co. 859	
Danallith Aktieselskab 859	
Culture media employed in bacteriological examination of —. Neutral red-lactose-peptone media. Chamot and Sherwood 1026	
Determination of carbon dioxide in —. Tillmans and Heublein 938	
Determination of — by distillation. Besson 671	
Determination of hydrogen sulphide in — at the source. Ince 938	
Determination of nitrates in — in presence of chlorides. Gerike 904	
Determination of oxygen in — by Winkler's method. Brühns 160	
Determination of quantity of hypochlorite required to sterilise —. Massy 517	
Determination of strontium and lithium in —. Averitt 904	
Direct microscopical counting of bacteria in —. Nelson 470	
Disinfection of — by means of bleaching powder. Langer 733	
Distilling and evaporating —. (P) Forbes 940	
drinking; Disinfection of —. Dakin and Dunham 610	
for drinking and industrial purposes; Removal of iron and manganese from —. (P) Permutit-Filter Co. 665	
drinking-; Purifying —. (P) Elektro-Osmose A.-G. 402	
drinking; Removing taste due to algae in —. Houston -electrolysis apparatus. (P) Mueller and others 510, 892	
Electrolysis of —. (P) Sebille 892	
Electrolysis of — with gas holders dipping into the electrolyte. (P) Elektrizitäts A.-G. vorm. Schuck-ert und Co. 224	
Filtering jewellers' waste wash —. (P) Boland 518	
filters; Outlet or extraction pipes of —. (P) Lassen and Hjort 904	
-gas. See under Gas.	
Means for treating —. (P) Noble 303	
Mineral — for use in manufacture of leavened bread (P) Kohnan and others 401	
Obtaining pure — from salt water. (P) Evans and Benjamin 665	
pipes; Corrosion of steel —. Bradley 1071	
potable; Enumeration of <i>Bac. coli</i> in —. Bourdet 99	
Potable — for military purposes. Vila 564	
Preservation of solutions of iodine trichloride for purifying contaminated —. (P) Corbelli and Antolini 940	
under pressure; Density regulator for atomising — in lead sulphuric acid chambers. (P) Santa 548r	
Purification of —. (P) Hoover 1147r	
purifying apparatus; Electrolytic —. (P) Kynaston 518	
rain-; Dissolved oxygen in —. Richards 939	
Regulating and proportioning the feed of chemicals or like substances to —. (P) Earland Wood 90r	
rich in magnesium salts; Determination of nitrates in — by the phenolsulphonic acid method. Nichols 904	
sea-; Evaporators for — for use on board ship. (P) Weir, Ltd., and Latta 1121	
sea-; Protecting aluminium and its light alloys from corrosion by —. (P) Seligman and Williams .. 389	
sea-; Salt manufacture by solar evaporation of —. Palmer 502	
sea-; Winning metals from —. (P) Nagel 653	

Water—*cont.*

Search for typhoid and paratyphoid bacilli in —	232
Dienert and Mathieu	237
Separating — from oil. (P) Sands	940
softeners; Chemical-feeding device for —. (P) Cartwright	161
softeners; Production of —. (P) Widner, and Des Moines Refining Co.	302
softening: (P) Blumenthal	161
(P) Linden	401
(P) Oelwerke Stern-Sonneborn A.-G.	518
softening; Apparatus for —. (P) Gibbs	910
softening; Discussion on —	83
softening; Manufacture of silicon compounds for —. (P) Boehringer, and Staten Island Chemical Corporation	564
softening and purifying apparatus. (P) Paterson	1256
softening; Rate of — by the lime-soda process. Wood	45r
softening reagents; Automatic regulation of supply of —. (P) Player and Weddell	611r
Sterilising —. (P) Burgess Laboratories	940
still. (P) Crispell	99r
supplies; Sterilisation of —. (P) Linden	99
supply; Decolorisation of, and removal of manganese from a —. Klut	905r
Treatment of —. (P) Menzies	1108 r
Treatment of — for softening, purifying, and like purposes. (P) Magrath	233r
Treatment of — for softening, sterilising, and like purposes. (P) Magrath	977
Use of copper sulphate in the destruction of algae in —. Embrey	395
Water-glass paints; Preparation of — which in use quickly become waterproof. (P) Gallenkamp	504r
Waterproof building material. (P) De Caudenberg	1010r
cement; Manufacture of —: (P) Meigs, and Electro-Chemical Supply and Engineering Co.	504
(P) Wedge, and Electro-Chemical Supply and Engineering Co.	959
fabrie and coating. (P) Adams	1092
material; Manufacture of —: (P) McIntosh, and Diamond State Fibre Co.	132
(P) Tate, and Tate Electrolytic Waterproofing Co.	514

phenylsulphonate; Volumetric determination of —. Adant	1194
phosphide; Determination of phosphorus in —. Liberi	652
sulphate; Manufacture of — from zinc ores: (P) Ferraris	137
(P) Llopert	138r, 712r
sulphate solutions; Purifying — for use in production of pigments. (P) Llopert	970r
sulphide; Volumetric determination of zinc in —. Sjöström	82
sulphide; Phosphorescent —. MacDougall and others	1046
sulphide; Process for oxidising —. (P) Aarts	962
Zinc-d sheet from scrap; Manufacture of iron from —. (P) Schleimer, and Albert Chem. Fabr.	145r
Zingerone, a new ketone occurring in ginger. Nomura ..	1062
Synthetic preparation of —. Layworth and Wykes ..	1063
Zirconia and alumina; Abrasive composition containing —. (P) Saunders and others	1130
Compounds of — with sulphuric acid. Chauvenet ..	711
Influence of size of granules on action of hydrochloric acid on —. Podszus	925
objects; Preparation of —. Ruff and Lauschke ..	85
Melting — and production of ware therefrom. Podszus ..	217
Use of — as refractory material. Audley	551
Zirconium-nickel alloys; Analysis of —. Kelley and Myers	1132
Preparation of pure —. Podszus	1012
Production of alloys of — with tungsten, molybdenum, tantalum, etc. (P) Podszus	929
Zirconium oxide; Manufacture of pure — free from iron. (P) Leuchs	503
salts; Properties and constitution of some new basic —. Rodd	710
Zircanyl acid sulphate. Chauvenet	871
bromides. Chauvenet	644
sulphates. Chauvenet	871
Znuprimum; Utilisation of —	1200
Zymase in the storage organs of the potato and sugar beet. Bodrář	97
Zymun; Conditions of activation of washed —. Harden ..	731

LIST OF NEW BOOKS RECEIVED.

	PAGE
Alkali, etc., works; Fifty-third annual report on — by the Chief Inspector. Proceedings during the year 1916	980
Analysis; A textbook of quantitative chemical —. Cumming and Kay	50
Blast furnaces. Safe practice at —. Willcox	240
Cement industry; The Portland —. Brown	50
Central; The —. Vol. XIII. No. 39. Special Chemical Department number	102
Chemical engineer; The training and work of the	946
Chemists' year book. Attack	522
Chimica analitica applicata; Trattato di —. Vol. II. Villavecchia	736
Coal; Methods of sampling delivered — and specifications for purchase of coal for the Government. Pope	240
Coal-mine fatalities in the United States, 1916. Fay	946
Dispenser; How to become a —. A new profession for women. Forster	946
Dyeing in Germany and America. Higgins	50
Dyestuffs; The chemistry of —. Fort and Lloyd	672
Explosives. Marshall	738
Explosives; Forty-first annual report of His Majesty's Inspectors of —. 1916	738
Explosives; Production of — in the United States during 1915. Fay	240
Export; Prohibitions of — in force in British India, the self-governing Dominions, Egypt, and certain other British Possessions	166
Flotation; Concentrating ores by —. Hoover	522
Flotation process; The —. Rickard	522
Food supply of the United Kingdom; Report of Royal Society Committee	308
Gas chemists' handbook	522
Gas testing; Standard methods of —. U.S. Bureau of Standards	240
Gold dredging in Montana; The history and development of —. Jennings	240
Health conservation at steel mills. Watkins	240
Imperial Institute Bulletin. Vol. XIV. No. 3	50
Industrial and manufacturing chemistry. Martin:	
Part II. Inorganic. Vol. I.	308
Vol. II.	946
Larkspur poisoning of livestock. Marsh and others	240
Marble quarrying; The technology of —. Bowles	240
Metal-mine accidents in the United States during 1915. Fay	946
Metalli; Combinazioni chimiche fra —. Gina e Gina-Sollini	738
Mines and quarries. General report, with statistics, for 1915, by the Chief Inspector of Mines. Part II.—Labour.	
Part III.—Output	356
National Physical Laboratory: Collected researches. Vol. XIII. 1916	1156
Report for the year 1916-17	1156
Nickel commission; Royal Ontario —. Report and appendix. 1917	946
Oil and gas fields; Underground wastes in — and methods of prevention. McMurray and Lewis	240
Ore sampling conditions in the West (U.S.A.). Woodbridge	240
Pharmacopœia; Changes in the U.S. — and in the National Formulary. Wilbert	980
Pharmacy; Year-book of —, and transactions of the British Pharmaceutical Conference, July 12, 1916.	166
Research; Industrial — in the United States. Fleming	672
Research; Report of the Committee of the Privy Council for Scientific and Industrial — for the year 1916	980
Soil types as found in the island of Hawaii; A study of the principal plantation —. Burgess	980
Sulphuric acid and alkali; The manufacture of —. Supplement to Vol. I. Lunge	522
Technical chemists' handbook. Lunge	308
Trade products of the British Empire	738
Trading with the enemy	166, 738

LIST OF JOURNALS ABSTRACTED. WITH ABBREVIATIONS USED, AND ADDRESSES OF PUBLISHERS AND PRICES.

JOURNAL.	ABBREVIATION.	ADDRESS OF PUBLISHER AND PRICE.*
Agricultural Bulletin of the Federated Malay States	Agric. Bull. F.M.S. ..	Dept. of Agriculture, Kuala Lumpur, F.M.S. 1s. 3d.
Agricultural Journal of India ..	Agric. J. India ..	W. Thacker and Co., 2, Creed Lane, London. 3s.
Agricultural Ledger	Agric. Ledger ..	Reporter on Economic Products to the Government of India, Calcutta.
Agricultural Research Institute, Pusa, Report and Bulletins.	Rep. (Bull.) Agric. Res. Inst., Pusa.	Supt. Govt. Printing, Calcutta. Price varies.
Allgemeine Zeitschrift für Bierbrauerei und Malzfabrikation ..	Allgem. Z. Bierbrau. u. Malzfabr.	Michaelerstrasse 25, Vienna XVIII/1. Krono 12 per annum.
American Journal of Pharmacy	Amer. J. Pharm. ..	115, North Tenth Street, Philadelphia, Pa., U.S.A. 30 cents.
American Journal of Science ..	Amer. J. Sci. ..	New Haven, Conn., U.S.A. 50 cents.
Analyst	Analyst	Simpkin, Marshall, Hamilton, Kent, and Co., Ltd., 2, 4, 6, S. Orange Street, London, S.W. 2s.
Annalen der Chemie	Annalen	C. F. Winter'sche Verlagshandlung, Leipzig, Germany. Per annum; M. 28.
Annales de Chimie Analytique ..	Ann. Chim. Analyt. ..	M. Crillon, 20, Boulevard Richard-Lenoir, Paris, 1 fr.
Annales des Falsifications ..	Ann. Falsif. ..	56, Rue Madame, Paris, 6c. 3 fr.
Annali di Chimica Applicata ..	Annali Chim. Appl. ..	Via Panisperna N, 89b, Rome. Lire 34 per annum.
Annali della R. Stazione Chimico Agraria Sperimentale di Roma	Ann. R. Staz. Chim. Agrar. Sperm. Roma	R. Stazione Chimico-Agraria Sperimentale di Roma, Rome.
Apotheker-Zeitung	Apoth.-Zeit. ..	Levetzowstrasse 16b, Berlin, N.W. 87. 25 Pf.
Archiv der Pharmazie	Arch. Pharm. ..	Selbstverlag des Deutschen Apotheker-Vereins, Berlin, Germany. M. 12 per annum.
Atti della Reale Accademia dei Lincei, Roma	Atti R. Accad. dei Lincei, Roma	Tipografia della R. Accademia dei Lincei, Rome. Lire 10 per annum.
Australasian Pharmaceutical Notes and News	Austr. Pharm. Notes and News	Elliott Bros., Ltd., O'Connell St., Sydney, N.S.W. 3d.
Berichte der Deutschen Chemischen Gesellschaft	Ber.	R. Friedländer und Sohn, Karlstrasse 11, Berlin, N.W. 6, Germany. M. 32 per annum.
Berichte der Deutschen Pharmazeutischen Gesellschaft ..	Ber. d.ents. Pharm. Ges.	Verlag von Gebr. Bornträger, Berlin, W. 35, Schöneberger Ufer 12a, Germany. M. 20 per annum.
Berichte des Ohara Instituts für landwirtschaftliche Forschungen	Ber. Ohara Inst. landw. Forsch.	Verlag der Ohara Schiō-ōkai, Kuraschiki, Provinz Okayama. 1 yen.
Biedermann's Zentralblatt für Agrkultur Chemie	Biedermann's Zentr. ...	O. Leiner, Königstrasse 26b, Leipzig, Germany. M. 22 per annum.
Bio-chemical Journal	Bio-chem. J.	Cambridge University Press, Fetter Lane, London, E.C. 7s.
Biochemische Zeitschrift	Biochem. Zeits. ..	Verlag von J. Springer, Berlin, W. 9, Linkstrasse 23/24. M. 14 per volume.
Blast-Furnace and Steel Plant ..	Blast-Furnace and Steel Plant	Thaw Building, 108, Smithfield St., Pittsburgh, U.S.A. 15 cents.
Board of Trade Journal	Bd. of Trade J. ..	Messrs. Wyman and Sons, Fetter Lane, London, E.C. 3d.
Brewers' Journal	Brewers' J.	F. W. Lyon, Eastcheap Buildings, Eastcheap, London, E.C. 2s.
British and Colonial Pharmacist	Brit. and Col. Pharm.	194-200, Bishopsgate, London, E.C. 1s.
Bulletin de l'Association Chimique de Sucre et de Distillerie	Bull. Assoc. Chim. Sucri.	156, Boulevard Magenta, Paris, 10e, France. 2 fr.
Bulletin of the Bureau of Agricultural Intelligence and of Plant Diseases	Bull. Bureau Agric. Intell.	International Institute of Agriculture, Rome. 2 fr.
Bulletin of the Forest Experiment Station, Meguro, Tokyo.	Bull. Forest Exp. Stat. Meguro.	Bureau of Forestry, Dept. of Agriculture and Commerce, Tokyo.
Bulletin of the Kentucky Agricultural Experiment Station	Bull. Kentucky Agric. Exp. Stat.	University of Kentucky, Lexington, Ky., U.S.A.
Bulletin of the School of Mines and Metallurgy, University of Missouri.	Bull. School Mines and Met., Univ. Missouri.	Director of Mining Experiment Station, Rolla, Mo., U.S.A.
Bulletin de la Société Chimique de Belgique	Bull. Soc. Chim. Belg.	M. J. Wauters, Palais du Midi (Galerie du Travail, 7), Brussels.
Bulletin de la Société Chimique de France	Bull. Soc. Chim. ..	Masson et Cie., 120, Boulevard Saint-Germain (6c), Paris. 38 fr. per annum.
Bulletin de la Société Française de Photographie	Bull. Soc. Franç. Phot.	51, Rue de Clichy, Paris, 9c. 1 fr. 50.
Bulletin de la Société Industrielle du Nord de la France	Bull. Soc. Ind. Nord	Rue de l'Hôpital Militaire 116, Lille, France.
Bulletin de la Société Industrielle de Mulhouse	Bull. Soc. Ind. Mulhouse	Berger-Levrault et Cie., 5, Rue des Beaux-Arts, Paris. 60 fr. per annum.

* The price for single copies is given where these are sold separately. In other cases, it is only possible to buy the Journals in question in complete volumes.

JOURNAL	ABBREVIATION.	ADDRESS OF PUBLISHER AND PRICE.
Bulletin de la Société d'Encouragement pour l'Industrie Nationale	Bull. Soc. d'Encour. ..	Secrétariat, Rue de Rennes 44, Paris, France. 36 fr. per annum.
Le Caoutchouc et le Gutta-Percha	Caoutchouc et Gutta-Percha	A. D. Cillard fils, 49, Rue des Vinaigriers, Paris, X. 30 fr. per annum.
Chamber of Commerce Journal ..	Ch. of Comm. J. ..	Oxford Court, Cannon Street, London, E.C. 6d.
Chemical News	Chem. News	E. J. Davey, 16, Newcastle Street, Farringdon Street, London, E.C. 4d.
Chemical Trade Journal	Chem. Trade J. ..	Davis Bros., Danes Inn House, 265, Strand, London, W.C. 6d.
Chemiker-Zeitung	Chem.-Zeit.	Dr. v. Vietinghoff-Scheel, Cöthen, Anhalt, Germany. M. 28 per annum.
Chemisch Weekblad	Chem. Weekblad ..	D. B. Centen, O.Z. Voorburgwal 115, Amsterdam. 10 fr. per annum.
Chemische Industrie	Chem. Ind.	Weidmann'sche Buchhandlung, Zimmerstrasse 94, Berlin, S.W., Germany. M. 20 per annum.
Chemische Revue über die Fett- und Harz-Industrie	Chem. Rev. Fett-Ind.	Dr. L. Allen, Catharinenstrasse 25, Hamburg, Germany. M. 1.75.
Chemisches Zentralblatt	Chem. Zentr.	R. Friedländer und Sohn, Karlstrasse 11, Berlin, N.W. 6, Germany. M. 80 per annum.
Chemist and Druggist *	Chem. and Drug. ..	42, Cannon Street, London, E.C. 6d.
Collegium	Collegium	K. Schorlemmer, Sebastian-Münster-Strasse 28, Worms am Rhein, Germany. 2s.
Collegium (London)	Collegium (London) ..	M. C. Lamb, 176, Tower Bridge Road, London, S.E. 2s.
Communications of the Netherland Government Institute for advising the Rubber Trade and Rubber Industry	Comm. Netherland Govt. Inst. for advising Rubber Trade	
Comptes-Rendus hebdomadaires des Séances de l'Académie des Sciences	Comptes rend. ..	Imprimerie Gauthier-Villars, Quai des Grands Augustins 55, Paris. 44 fr. per annum.
Comptes-Rendus des Travaux de Laboratoire de Carlsberg	Comptes-rend. Trav. Lab. Carlsberg	H. Hagerup, Copenhagen. Price varies.
Deutsche Zuckerindustrie	Deuts. Zuckerind. ..	Verlag der Gesellschaft, Die Deuts. Zuckerindustrie, Berlin. M. 24 per annum.
Elektrochemische Zeitschrift ..	Elektrochem. Zeits. ..	F. Siemenroth, Hafenplatz 9, Berlin, S.W. 11. M. 1.50.
Engineering	Engineering	C. R. Johnson, 35 and 36, Bedford Street, Strand, London, W.C. 9d.
Engineering and Mining Journal ..	Eng. and Min. J. ..	McGraw Hill Publishing Co., 10th Avenue at 36th Street, New York City. 15 cents.
Färber-Zeitung	Färber-Zeit.	Julius Springer, Linkstrasse 23/21, Berlin, W. Germany. M. 18.40 per annum.
Ferrum	Ferrum	W. Knapp, Mühlweg 19, Halle on Saale, Germany. M. 22 per annum.
Feuerungstechnik	Feuerungstechnik ..	O. Spamer, Täubchenweg 26, Leipzig-R., Germany. M. 4.80 per annum.
Foreign Office Annual Series (Cons. Reports)	F. O. Ann. Series ..	Wyman and Sons, Fetter Lane, London, E.C. 1 1/2d. to 6d.
Gas Journal	Gas J.	W. King, 11, Bolt Court, Fleet Street, London, E.C. 6d.
Gazzetta Chimica Italiana	Gazz. Chim. Ital. ..	La Direzione della "Gazzetta Chimica," Via Panisperna, 89, Rome. Lire 4.
Gerber	Gerber	VI 1/2 Gumpendorferstrasse 89, Wien, Austria. Kr. 17.50 per annum.
Gummi-Zeitung	Gummi-Zeit.	Geschäftsstelle der "Gummi-Zeitung," Blücherstrasse 31, Berlin, S. 61, Germany. M. 16 per annum.
Imperial Institute Bulletin ..	Bull. Imp. Inst. ..	John Murray, Albemarle Street, London, W. 2s. 6d.
India-Rubber Journal	India-rubber J. ..	Maclaren and Sons, 37 and 38, Shce Lane, London, E.C. 3d.
International Sugar Journal ..	Int. Sugar J.	2, St. Dunstan's Hill, London, E.C. 1s. 4d.
Internationale Zeitschrift für Metallographie	Internat. Z. Metallog.	Gebr. Bornträger, Schöneberger Ufer 12a, Berlin, W. 35. M. 40 per annum.
Journal of Agricultural Research	J. Agric. Res.	U.S. Department of Agriculture, Washington, D.C., U.S.A. Price varies.
Journal of Agricultural Science ..	J. Agric. Sci.	University Press, Cambridge. 5s.
Journal of the American Chemical Society	J. Amer. Chem. Soc.	C. L. Parsons, Box 505, Washington, D.C., U.S.A. 60 cents.
Journal of the American Leather Chemists' Association	J. Amer. Leather Chem. Assoc.	American Leather Chemists' Assoc., Easton, Pa., U.S.A. 50 cents.
Journal of the Association of Official Agricultural Chemists	J. Assoc. Off. Agric. Chem.	Williams and Wilkins Co., Baltimore, U.S.A., and Cambridge University Press, Fetter Lane, London, E.C. \$5 per annum.
Journal of Biological Chemistry ..	J. Biol. Chem.	2419-21, Greenmount Avenue, Baltimore, Md., U.S.A. \$3.25 per vol.

JOURNAL.	ABBREVIATION.	ADDRESS OF PUBLISHER AND PRICE.
Journal of the Board of Agriculture	J. Board Agric. ..	Board of Agriculture and Fisheries, Whitehall Place, London, S.W. 4d.
Journal of the Canadian Mining Institute	J. Canad. Min. Inst.	3 and 4, Windsor Hotel, Montreal, Canada.
Journal of the Chemical Society of London, Transactions	Ch. m. Soc. Trans.	Gurney and Jackson, 33, Paternoster Row, London E.C. Trans. 5s.
Journal of the Chemical, Metallurgical, and Mining Society of South Africa.	J. Chem. Met. Soc., S. Africa.	F. Rowland, Old Municipal Buildings, De Villiers Street, Johannesburg. 3s.
Journal de Chimie Physique ..	J. Chim. Phys ..	Gauthier-Villars, 55, Quai des Grands Augustins, Paris. 25 fr. per annum; the price of a single copy varies according to the size.
Journal of the College of Agriculture Tokyo Imperial University, Japan	J. Coll. Agric., Tokyo	Director of the College of Agriculture, Tokyo Imperial University, Japan. Price varies.
Journal of the College of Engineering, University of Tokyo	J. Coll. Eng., Univ. Tokyo	The University, Tokyo.
Journal of the College of Science, Imperial University of Tokyo	J. Coll. Science, Tokyo	Director of the College of Science, Tokyo Imperial University, Japan. Price varies.
Journal of the Franklin Institute	J. Franklin Inst. ..	The Actuary, The Franklin Institute, Philadelphia, Pa., U.S.A. 50 cents.
Journal für Gasbeleuchtung und Wasserversorgung	J. Gasbeleucht. ..	R. Oldenbourg, Glückstrasse 8, München, Germany. M. 20 per annum.
Journal of Industrial and Engineering Chemistry	J. Ind. Eng. Chem. ..	C. L. Parsons, Box 505, Washington, D.C., U.S.A. 60 cents.
Journal of the Institute of Brewing	J. Inst. Brewing ..	Harrison and Sons, 45, Pall Mall, London, W. 4s.
Journal of the Institution of Mechanical Engineers ..	J. Inst. Mech. Eng. ..	Storey's Gate, Westminster, S.W.
Journal of the Institution of Petroleum Technologists	J. Inst. Petroleum Tech.	The Institution, 17, Gracechurch Street, London, E.C. 5s.
Journal of Physical Chemistry ..	J. Phys. Chem. ..	W. D. Bancroft, Ithaca, N.Y., U.S.A. \$4 per annum.
Journal de Pharmacie et de Chimie	J. Pharm. Chim. ..	O. Doin et fils, Place de l'Odéon, Paris, 8. 20 fr. per annum.
Journal für praktische Chemie ..	J. prakt. Chem. ..	J. A. Barth, Dörrienstr. 16, Leipzig, Germany. M. 26.50 per annum.
Journal of the Royal Society of Arts	J. Soc. Arts	G. Bell and Sons, York House, Portugal Street, London, W.C. 6d.
Journal of the Russian Physical-chemical Society	J. Russ. phys. chem. Soc.	Laboratoire de Chimie, Université Impériale, Petrograd, Russia. R. 1.50.
Journal of the Society of Dyers and Colourists	J. Soc. Dyers and Col.	Pearl Assurance Buildings, Market Street, Bradford, Yorks. 2s.
Journal of the Society of Glass Technology	J. Soc. Glass Technol.	Dr. W. E. S. Turner, The University, Sheffield. 7s. 6d.
Journal of the Society of Leather Trades' Chemists	J. Soc. Leather Trades' Chem.	H. Brumwell, The University, Leeds. 2s.
Journal of the Textile Institute ..	J. Text. Inst. ..	J. D. Athey, 16, St. Mary's Parsonage, Manchester. 3s.
Journal of the Washington Academy of Sciences	J. Wash. Acad. Sci. ..	2419, Greenmount Avenue, Baltimore, Md., U.S.A. 25 cents; 50 c. for July, Aug., and Sept. numbers.
Kōgyō-Kwagaku-Zasshi (Journal of Chemical Industry, Japan)	Kōgyō-Kwagaku-Zasshi (J. Chem. Ind. Japan)	Kōgyō-Kwagaku-Kwai, Iidamachi, Kojimachi-ku, Tokyo. 5 yen. (10s. 3d.) per annum.
Kolloid-Zeitschrift	Kolloid-Zeits.	T. Steinkopff, Bismarckplatz 16, I., Dresden-A, 14, Germany. M. 3—4.
L'Industria Chimica	L'Ind. Chimica ..	Associazione Chimica Industriale, Via Roma 28 (Galleria Nazionale Scala A), Turin, Italy. Lira 1.
Mededeelingen van het Central Rubberstation	Mededeel. Centr. Rubberstat.	The University, Kyoto, Japan. Price varies.
Memoirs of the College of Science and Engineering, Kyoto Imperial University	Mem. Coll. Sci. and Eng. Kyoto Imp. Univ.	W. Thacker and Co., 2, Creed Lane, London. Price varies.
Memoirs of the Department of Agriculture in India	Mem. Dept. Agric. India	Gauthier-Villars, 55, Quai des Grands Augustins, Paris. \$2.
Mémoires des Poudres et Salpêtres	Mém. Poudres et Salpêtres	W. Knapp, Mühlweg 19, Halle on Saale, Germany. M. 28 per annum.
Metall und Erz	Metall u. Erz	McGraw Publishing Co., Tenth Avenue at 36th Street, New York City, U.S.A. 25 cents.
Metallurgical and Chemical Engineering	Met. and Chem. Eng.	Julius Springer, Linkstrasse 23/24, Berlin, W. 9, Germany. M. 16 per annum.
Mittheilungen aus dem königlichen Materialprüfungsamt zu Gross-Lichterfelde West	Mitt. k. Mater. prüf.	Prof. Dr. W. Will, Neu-Babelsberg, bei Berlin, Germany.
Mittheilungen aus der Centralstelle für wissenschaftlich-technische Untersuchungen	Mitt. Centralst. Wiss.-techn. Unters.	

JOURNAL.	ABBREVIATION.	ADDRESS OF PUBLISHER AND PRICE.
Mittheilungen des k. k. Technischen Versuchsamtes	Mitt. k. k. Techn. Versuchsamtes	Verlag der k. k. Hof- und Staatsdruckerei, Wien, Austria.
Monatshefte für Chemie der kaiserlichen Akademie der Wissenschaften, Wien	Monatsh. Chem. ..	A. Hölder, Rothenthurmstrasse 25, Wien I, Austria. M. 16.50 per annum.
Moniteur Scientifique	Monit. Scient. ..	Dr. G. Quesneville, 12, rue de Buci, Faubourg St. Germain, Paris. 2 fr.
New Zealand Journal of Science and Technology	N.Z.J. Sci. and Technol	The Director, Dominion Museum, Wellington, N.Z. 1s. 6d.
Oesterreichische Zeitschrift für Berg- und Hüttenwesen	Oesterr. Z. Berg- u. Hüttenw.	Kohlmarkt 20, Wien I, Austria. Kr. 28 per annum.
Oil, Paint, and Drug Reporter ..	Oil, Paint, and Drug Rep.	100, William Street, New York City, U.S.A. \$5 per annum, U.S.A., \$6 Canada, \$7 other countries.
Paper Making	Paper Making ..	5, Ludgate Circus Buildings, E.C. 5s. per annum.
Papier-Fabrikant	Papierfabr. ..	Otto Elsner, Oranienstr. 140-142, Berlin, S. 42. 50 Pf.
Perfumery and Essential Oil Record	Perfumery and Essent. Oil Rec.	6, Serle Street, London, W.C. 1s.
Petroleum	Petroleum	Verlag für Fachliteratur, Motzstrasse 8, Berlin, W. 30. M. 1.50.
Pharmaceutical Journal	Pharm. J. ..	150, Holborn, London, E.C. 6d.
Pharmaceutisch Weekblad ..	Pharm. Weekblad ..	D. B. Centen, O.Z. Voorburgwal 115, Amsterdam. 10 fr. per annum.
Pharmazeutische-Zeitung ..	Pharm.-Zeit. ..	Link-Strasse 23-24, Berlin, W. 9.
Pharmazeutische Zentralhalle ..	Pharm. Zentralh. ..	Dr. A. Schneide, Schandauer Strasse 43, Dresden A, 21.
Philippine Journal of Science ..	Philippine J. Sci. ..	Bureau of Science Manila, Philippine Islands. 50 cents.
Philosophical Magazine and Journal of Science	Phil. Mag.	Taylor and Francis, Red Lion Court, Fleet Street, London, E.C. 2s. 6d.
Photographic Journal	Phot. J.	Harrison and Sons, 45, Pall Mall, London, S.W. 1s.
Proceedings of the American Society of Civil Engineers	Proc. Amer. Soc. Civ. Eng.	220, West 57th Street, New York City, U.S.A. \$8 per annum.
Proceedings of the Australasian Institute of Mining Engineers	Proc. Austral. Inst. Min. Eng.	57-59, Swanston Street, Melbourne, Victoria, Australia.
Proceedings of American Society for Testing Materials	Proc. Amer. Soc. Test-ing Materials	McGraw Hill Book Co., 239 W. 39th Street, New York.

LIST OF ERRATA, 1917.

No. of Journal.	Page.	Column.	Line from Top.	Line from Bottom.	Errata.
No. 1—Jan. 15	28	1	..	35	For "Kelvin" read "Kevlin."
" "	32	2	..	37	Insert "F. C. Frary," name of patentee.
" "	34	2	17	..	For "C. H. Guillaume" read "C. E. Guillaume."
No. 2—Jan. 31	93	2	19	..	For "17,702" read "17,202."
No. 4—Feb. 28	202	1	24	..	For "Gessell" read "Gesell."
" "	209	2	..	12	For "van" read "von."
" "	220	1	..	19	For "0-0200c. (0-01045d.)" read "0-2c. (0-1d.)"
" "	233	1	..	4	For "G. P." read "J. P."
No. 5—Mar. 15	271	2	..	23 and 27	For "by the addition of phenol in which the . . . " read "by means of phenol of which the viscosity at different . . ."
" "	272	1	..	18	For "jet was moved" read "pipette was movable."
" "	272	1	..	12	Delete this line
" "	272	1	..	11	Delete "bottom."
" "	272	1	..	11	For "main" read "mean."
" "	272	1	..	7	After "viscosity" add "within the limited range chosen here."
" "	297	2	11	..	For "275,421" read "295,421."
No. 6—Mar. 31	347	2	..	15	For "Rendall" read "Randall."
No. 7—Apr. 16	379	1	11	..	For "1,212,991" read "1,212,291."
" "	382	1	18	..	For "103,709" read "103,739."
No. 8—Apr. 30	447	1	12	..	For "F. G. Lea" read "E. G. Lea."
" "	457	2	26	..	For "1,216,590" read "1,216,390."
" "	474	1	..	18	For "Davies" read "Davis."
No. 9—May 15	590	2	21	..	For "McCulloch" read "McNulloh."
" "	520	2	..	29	For "1,209,575" read "1,219,575."
No. 11—June 15	585	2	..	4	For "Bart" read "Bartl."
" "	615	2	18	..	For "105,350" read "105,380."
No. 13—July 16	736	2	30	..	For "0-1622" read "1-0622."
No. 15—Aug. 15	880	2	..	33	For "H. A. Ashenhurst" read "H. S. Ashenhurst."
" "	888	1	17	..	For "S. W. Lawrie" read "J. W. Lawrie."
No. 16—Aug. 31	925	2	..	5	For "1,231,741" read "1,231,471."
" "	933	2	..	10	For "Toret" read "Joret."
" "	938	1	22	..	For "1,203,364, 1,203,365, and 1,203,366," read "1,230,364 1,230,365, and 1,230,366."
No. 18—Sept. 29	999	2	8	..	For "Born" read "Born."
No. 19—Oct. 15	1051	1	..	19	For "microscopic" read "macroscopic."
No. 20—Oct. 31	1088	2	7	..	For "Mass" read "Moss."
" "	1088	2	..	32	For "Westby" read "Westly."
No. 21—Nov. 15	1137	1	3	..	For "McGraham" read "McGahan."
No. 22—Nov. 30	1171	1	15	..	For "1906" read "1916."
" "	1185	1	2	..	For "J. R." read "G. R."
No. 23—Dec. 15	1216A	1	..	13	For "not" read "now."
" "	1227	2	33	..	For "M. B. Lamb" read "M. R. Lamb."
" "	1228	1	30	..	For "P. Bingham" read "C. Bingham."
" "	1228	1	..	24	For "Wilcox" read "Wilcox."
" "	1232	2	16	..	For "1,243,327" read "1,242,327."
No. 24—Dec. 31	1266	2	26	..	For "Dri fein" read "Dreifin."

Journal of the Society of Chemical Industry.

No. 1, Vol. XXXVI.

JANUARY 15, 1917.

No. 1, Vol. XXXVI.

The Society of Chemical Industry.

Past Presidents.

† Rt. Hon. Sir Henry Roscoe, LL.D., F.R.S.	1881—1882.
† Sir Frederick A. Abel, Bart., F.R.S.	1882—1883.
† Walter Weldon, F.R.S.	1883—1884.
† Sir Wm. H. Perkin, LL.D., Ph.D., F.R.S.	1884—1885.
E. K. Muspratt, LL.D.	1885—1886.
† David Howard.	1886—1887.
Sir James Dewar, M.A., LL.D., F.R.S.	1887—1888.
† Ludwig Mond, Ph.D., F.R.S.	1888—1889.
† Sir Lowthian Bell, Bart., F.R.S.	1889—1890.
† E. Rider Cook.	1890—1891.
J. Emerson Reynolds, M.D., D.Sc., F.R.S.	1891—1892.
† Sir John Evans, K.C.B., F.R.S.	1892—1893.
† E. C. C. Stanford.	1893—1894.
Sir Edward Thorpe, C.B., LL.D., F.R.S.	1894—1895.
Thomas Tyrer.	1895—1896.
† Edward Schunck, Ph.D., F.R.S.	1896—1897.
Frank Clowes, D.Sc.	1897—1898.
Sir George T. Beilby, LL.D., F.R.S.	1898—1899.
C. F. Chandler, D.Sc., M.D., Ph.D., LL.D.	1899—1900.
† Sir Jos. W. Swan, D.Sc., M.A., F.R.S.	1900—1901.
† Ivan Levinstein.	1901—1903.
† Sir Wm. Ramsay, K.C.B., D.Sc., F.R.S.	1903—1904.
Wm. H. Nichols, M.S., LL.D., D.Sc.	1904—1905.
† Edward Divers, M.D., D.Sc., F.R.S.	1905—1906.
† Enstace Carey.	1906—1907.
Sir Boverton Redwood, Bart., D.Sc.	1907—1908.
† Raphael Meldola, F.R.S.	1908—1909.
Prof. Ira Remsen.	1909—1910.
Walter F. Reid.	1910—1911.
Rudolph Messel, Ph.D., F.R.S.	1911—1912.
Prof. Marston T. Bogert, LL.D.	1912—1913.
Sir William Crookes, O.M., F.R.S.	1913.
Rudolph Messel, Ph.D., F.R.S.	1914.
Prof. G. G. Henderson, LL.D., D.Sc., F.R.S.	1914—1915.
† Deceased.	

LIST OF COUNCIL, 1916-17.

President: Dr. Charles Carpenter.

Vice-Presidents:

Prof. E. C. C. Baly, F.R.S.	D. Lloyd Howard.
R. H. Clayton.	Julius Huebner.
Sir William Crookes, O.M., F.R.S.	Prof. H. Louis.
Prof. F. G. Donnan, F.R.S.	W. H. Nichols, LL.D.
Henry Hemingway.	Sir F. L. Nathan.
Prof. G. G. Henderson, F.R.S.	Harry Silvester.
Ordinary Members of Council:	
Dr. E. F. Armstrong.	R. D. Pullar.
Prof. H. E. Armstrong, F.R.S.	Dr. A. Rée.
J. H. Coste.	Walter F. Reid.
E. V. Evans.	Prof. R. F. Ruttan.
Prof. W. R. Hodgkinson.	A. Gordon Salaman.
E. Grant Hooper.	Joseph T. Wood.

Sectional Chairmen and Secretaries:

W. J. Rees.	BIRMINGHAM.	F. R. O'Shaughnessy.
T. H. Wardleworth.	CANADIAN.	Alfred Burton.
Prof. Jas. Walker, F.R.S.	EDINBURGH.	Dr. A. Lauder.
J. Macleod.	GLASGOW.	Dr. G. S. Cruikshanks.
John Gray.	LIVERPOOL.	Dr. Alfred Holt.
A. R. Ling.	LONDON.	T. D. Morson.
J. H. Roseason.	MANCHESTER.	L. E. Vlies.
H. Peile.	NEWCASTLE.	E. F. Hooper.
S. W. Wilder.	NEW ENGLAND.	Alan A. Claffin.
Jerome Alexander.	NEW YORK.	Dr. P. C. McIlhenny.
Dr. R. M. Caven.	NOTTINGHAM.	J. M. Wilkie.
H. G. Smith.	SYDNEY, N.S.W.	T. U. Walton.
Prof. J. W. Cobb.	YORKSHIRE.	Thomas Fairley.

Honorary Treasurer.

Thomas Tyrer, Stirling Chemical Works, Stratford, E.

Honorary Foreign Secretary:

Dr. R. Messel, F.R.S.

Secretary: Dr. J. P. Longstaff, Broadway Chambers, Westminster, S.W.

Telegraphic Address: "Induchem, Vic., London."
Telephone Number: 715 Victoria.

THE JOURNAL.

Publication Committee.

The President.

Julian L. Baker.	Charles A. Keane, D.Sc., Ph.D.
W. J. A. Butterfield.	A. R. Ling.
F. H. Carr.	W. Macnab.
C. F. Cross.	Rudolph Messel, Ph.D., F.R.S.
J. T. Dunn, D.Sc.	G. T. Morgan, D.Sc., F.R.S.
Edward V. Evans.	Prof. H. R. Procter.
T. Fairley.	Sir Boverton Redwood, Bart.
H. Hemingway.	W. J. Rees.
J. T. Hewitt, D.Sc., F.R.S.	Walter F. Reid.
W. R. E. Hodgkinson, Ph.D.	Watson Smith.
G. T. Holloway.	John Spiller.
E. Grant Hooper.	L. T. Thorne, Ph.D.
Julius Huebner.	Thomas Tyrer.

Editor:

T. F. Burton, 63, Melbury Gardens, West Wimbledon, S.W.

Sub-Editor:

A. Shonk.

Assisted by the following Staff of Abstractors:

E. W. Attack, M.Sc.	IV., VI.	Barker North	XI.
J. F. Briggs V.	XVII., XVIII.	J. P. Ogilvie	XVII.
T. Callan, M.Sc.	XII., XV., Ph.D.	R. G. Pelly V.	XII., XIII., XV.
J. E. Christopher	III., III.	T. H. Pope, B.Sc.	XVII., XVIII., XX.
W. H. Coleman	I., III.	W. E. F. Powney	II., X.
W. F. Frew	I., II.	W. R. Schoeller, Ph.D.	VII., X.
Walter C. Hancock, B.A.	VIII., IX.	A. B. Searle	II., VIII., IX.
J. H. Johnston, M.Sc.	XIX.	A. Shonk	III., VII., X., XI.
J. B. C. Kershaw	II., VII., XI.	W. P. Skertchly	XII., XIX.
J. H. Lane	XVII., XVIII., XXIII.	F. Southerton, B.Sc.	VII., XX.
E. W. Lewis	XIV.	F. Sproxton, B.Sc.	V., VII., XIII.
C. A. Mitchell, M.A.	XII., XXII.	T. Stenhouse, B.Sc.	X., XIII.
G. F. Morrell, Ph.D.	III., XVII.	A.R.S.M., F.I.C.	XIV.
		B. V. Storr, M.Sc.	XXI.
		F. C. Thompson	XV.
		E. H. Tripp, Ph.D.	VII., XVI., XXIII.

Birmingham Section.

Chairman: W. J. Rees.

Vice-Chairman: H. T. Pinnock.

Committee:

F. H. Alcock.	H. L. Heathcote.	T. Slater Price.
N. P. Booth.	O. F. Hudson.	E. C. Rossiter.
W. Clifford.	A. W. Knapp.	Harry Silvester.
J. E. Coates.	J. C. Mann.	
P. F. Frankland.	E. S. Morrell.	

Hon. Local Secretary and Treasurer:

F. R. O'Shaughnessy, 42, Temple St., Birmingham.

Canadian Section.

Chairman: T. H. Wardleworth.

Vice-Chairmen:

S. B. Chadsey, N. N. Evans, W. L. Goodwin.

Committee:

L. T. Acton.	J. A. De Cew.	Robt. Job.
J. W. Bain.	J. R. Donald.	Otto G. Palm.
J. S. Bates.	C. F. Heebner.	W. H. Thord.
D. G. Buchanan.	Milton L. Hersey.	

Hon. Treasurer: E. G. R. Ardagh.

Hon. Local Secretary:

Alfred Burton, 2-16, Liberty Street, Toronto.

Asst. Hon. Secretary for Montreal:

Joel B. Saxe, 171, St. James Street, Montreal.

Edinburgh Section.

Chairman: James Walker.

Vice-Chairman: D. B. Doff.

Committee:

J. G. Annan.	J. Rutherford Hill.	Wilfrid A. Sim.
J. F. Briggs.	Jan. C. Irvine.	Alan Smith.
J. D. Brunton.	D. S. Jordan.	S. Stewart.
L. Dobbin.	A. P. Laurie.	H. F. Watt.

Hon. Local Secretary:

A. Lauder, 13, George Square, Edinburgh.

Glasgow Section.

Chairman : James Macleod.
Vice-Chairman : Quintin Moore.

Committee :

E. G. Beckett.	Jas. Faill.	W. G. McKellar.
A. R. Berry.	Robert Hamilton.	J. McFarlane.
Thomas Callan.	T. H. P. Heriot.	G. T. Purvis.
R. M. Clark.	S. H. B. Langlands.	James Reid.
W. H. Coleman.	James Lawrence.	James Robertson.
Cecil H. Desch.		

Hon. Secretary and Treasurer :

G. S. Cruikshanks, Royal Technical College, Glasgow.

Liverpool Section.

Chairman : John Gray.
Vice-Chairman : E. C. C. Baly.

Committee :

A. Carey.	E. L. Peck.	W. P. Thompson.
P. de G. Coghill.	H. E. Potts.	G. Carruthers
J. Findlater.	A. T. Smith.	Thomson.
J. Harger.	Frank Tate.	Stuart J. Wilcox.
R. D. Mason.		

Hon. Treasurer :

Edwin Thompson, 25, Sefton Drive, Liverpool.

Hon. Local Secretary :

Alfred Holt, The University, Liverpool.

London Section.

Chairman : A. R. Ling.
Vice-Chairman : H. E. Armstrong.

Committee :

Julian L. Baker.	W. R. Hodgkinson.	J. W. McDonald.
W. A. Bone.	E. Grant Hooper.	Stephen Muir.
A. W. Crossley.	H. A. D. Jowett.	J. Gordon Parker.
E. V. Evans.	C. A. Keane.	R. Seligman.
J. T. Hewitt.	W. J. Leonard.	

Hon. Local Secretary and Treasurer :

T. D. Morson, 14, Elm Street, Gray's Inn Road, W.C.

Manchester Section.

Chairman : J. H. Hoscason.
Vice-Chairman : W. Thomson.

Committee :

J. Allpass.	L. Blundell.	A. Lapworth.
E. Arden.	Bertram Hart.	E. F. Morris.
B. F. Armstrong.	J. Hubner.	A. Worthington.
J. Baddiley.		

Hon. Local Secretary :

L. E. Vlies, Belmont, Gowan Road, Alexandra Park, Manchester.

Newcastle Section.

Chairman : H. Pelle.
Vice-Chairman : T. W. Lovibond

Committee :

P. P. Redson.	J. T. Dunn.	G. P. Lishman.
C. Badde.	F. C. Garrett.	J. H. Patter-on.
S. H. Collins.	T. Hardie.	H. D. Smith.
W. Diamond.		

Hon. Local Secretary :

B. F. Hooper, 10, The Elms West, Sunderland.

New England Section.

Chairman : S. W. Wilder.
Vice-Chairman : (vacant.)

Committee :

F. E. Atteaux.	C. L. Gagnebin.	W. K. Robbins.
C. G. Bird.	R. Hütz.	B. E. Schlesinger.
D. J. Danker.	H. P. Knapp.	H. J. Skinner.
W. C. Durfee.	W. D. Livermore.	W. S. Williams.
C. H. Fish.	L. A. Olney.	

Hon. Treasurer :

Frank W. Atwood, 216, Milk Street, Boston, Mass., U.S.A.

Hon. Local Secretary :

A. A. Clahm, 176, Federal Street, Boston, Mass., U.S.A.

New York Section.

Chairman : Jerome Alexander.
Vice-Chairman : C. E. Sholes.

Committee :

C. Baskerville.	D. W. Jayne.	Allen Rogers.
S. R. Church.	A. C. Langmuir.	Utley Wedge.
Carleton Ellis.	H. S. Miner.	M. C. Whitaker.
W. M. Grosvenor.	Gilbert Rigg.	H. Wigglesworth.
Martin H. Ittner.		

Hon. Treasurer : Frank C. R. Hemingway, Bonnd Brook, N.J., U.S.A.

Hon. Local Secretary :

P. C. Mellhiney, 50, East 41st Street, New York City, U.S.A.

Nottingham Section.

Chairman : R. M. Caven.
Vice-Chairmen : S. R. Trotman and John White.

Committee :

T. H. Adams.	B. Collitt.	C. E. B. Merriman.
L. Archbutt.	R. Duncalie.	A. Smith.
M. Barrowcliff.	J. H. Dunford.	J. T. Wood.
F. H. Carr.	F. Stanley Kipping.	

Hon. Treasurer :

S. J. Pentecost, Lenton Works, Nottingham.

Hon. Local Secretary :

J. M. Wilkie, 38, South Road, West Bridgford, Nottingham.

Sydney, N.S.W., Section.

Chairman : H. G. Smith.
Vice-Chairman : C. E. Fawsitt.

Committee :

R. W. Challinor.	R. Greig-Smith.	Loxley Meggitt.
F. A. Coombs.	G. Harker.	S. E. Sibley.
J. D. Granger.	A. B. Hector.	B. J. Smart.

Hon. Local Secretary and Treasurer :

Official Notices.

CROSS AND BEVAN ESSAY PRIZE OF £20 AND LATHAM RESEARCH GRANT OF £300.

The Council have pleasure in announcing that a gift of £20 has been made by Messrs. Cross and Bevan as a prize for an essay on "The Inter-connection of Economic Botany and Chemical Industry."

A further sum of £300 has also been presented by their friend, Mr. T. P. Latham, of Weybridge, to be paid in three annual instalments to such one of the competing essayists as may be judged to be of conspicuous ability, as a grant towards his expenses, on the condition that he apply himself, during three years, to research of approved character on a subject cognate with that discussed in his essay.

The immediate object of the donors is to promote the study of economic botany with special reference to its bearing on chemical industry, giving the widest possible interpretation of the relationship.

They desire, under the auspices of the Society, to assist in forming public opinion in this direction and to discover and further the career of a student of promise who may wish to devote himself to work in such a field.

The Essay Prize will be open to all members of the Society who are British subjects. The Research Grant will be limited to competitors under 25 years of age at the time of sending in the essay.

Essays are to be submitted to the Council of the Society not later than the close of the year 1917. The awards will be made promptly. Neither the prize nor the first grant will be given unless the essayist or essayists shall be deemed to have real merit. The Latham Research Student will be required to submit a report at the close of each year, to satisfy the Council that he has made and is likely to make proper use of the grant.

REPORTS OF THE PROGRESS OF APPLIED CHEMISTRY.

The first volume of the Reports of the Progress of Applied Chemistry is now in active preparation, and will, it is hoped, be published shortly. It will cover recent progress to the end of June, 1916. The second volume will deal with the period up to the end of 1917, and subsequently it is proposed to issue the Reports annually.

The Reports will present a critical summary of the progress that has been made in the various branches of chemical industry during the period in question. It has not been found practicable to treat every section of the Journal classification. Agricultural chemistry, the chemistry of foods, and analysis are fully dealt with in the admirable series of Reports issued annually by the Chemical Society, and for the present there will be no sections on general plant and explosives.

The following is a list of the subjects which will be dealt with, together with the names of the experts who are contributing to this volume:—

Fuel—J. W. Cobb,
Gas, destructive distillation, tar products—E. V. Evans.
Mineral oils—A. W. Eastlake,
Colouring matters and dyes—G. T. Morgan.
Fibres, paper, dyeing, printing—Julius Huebner.
Acids, alkalis, salts, etc.—H. A. Auden.
Glass, ceramics, cement, etc.—J. A. Audley.
Metals, metallurgy—W. R. E. Hodgkinson.
Electro-chemistry—J. T. Barker.

Fats, oils, waxes—G. H. Warburton.
Paints, pigments, varnishes, resins—R. S. Morrell.
Indiarubber—H. P. Stevens.
Leather, glue, etc.—J. T. Wood.
Sugar, starches—J. G. Macintosh.
Fermentation—A. R. Ling.
Sanitation, water purification—F. R. O'Shaughnessy.
Fine chemicals, medicinal substances, essential oils—F. L. Pyman.
Photographic materials and processes—B. V. Storr.

The price of issue will be, to members, 2s. 6d. (plus 6d. postage), and non-members, 5s. (plus 6d. postage). As the issue is to be a limited one, those desirous of securing copies are requested to fill in the order form attached to the cover of the Journal, and return it to the Secretary at an early date.

Glasgow Section.

Meeting held at Glasgow on Tuesday, November 28th, 1916.

MR. JAMES MCLEOD IN THE CHAIR.

THE THERMAL DECOMPOSITION OF LOW TEMPERATURE COAL TAR.

BY DAVID TREVOR JONES, M.Sc.

The mechanism of the process by which coal tar is formed in the gas retort has been the subject of much speculation and controversy. The various theories which have been propounded regarding this process resolve themselves into two classes: (1) those which assume that the components of coal tar are formed by the combination of various small molecules, such as acetylene, which are regarded as primary products of the destructive distillation, and (2) those which assume that the coal substance is itself essentially aromatic, and that the benzene and other aromatic distillates are themselves primary products of the breakdown of coal. This second theory has been put forward by Hensler (Ber., 1897, 30, 2744; this J., 1898, 37) as the result of observations made on bituminous coals, brown coals, and lignite. This theory that coal is a mixture of aromatic substances can only be upheld if observations are confined to its distillation products obtained at temperatures of 700° C. and upwards. Coal is certainly not aromatic in the structure of any of its chief components, though it must be admitted that but little is as yet known of its chemical nature. It is formed from decayed vegetable matter which has been subjected to very considerable pressure, and in many cases to such a degree of heat as would suffice to bring it to the stage of incipient distillation, i.e., between 250° C. and 300° C. This was argued on purely chemical grounds by Jones and Wheeler (Chem. Soc. Trans., 1914, 105, 143; this J., 1914, 192), who pointed out that certain English bituminous coals yielded on extraction with solvents the identical paraffin, C₂₇H₅₆, which they yielded in much larger quantity on distillation. They pointed out that a similar conclusion could be drawn from the earlier results of Pictet and Ramseyer (Ber., 1911, 44, 2486; this J., 1911, 1041, 1199), who extracted from a Montrambert coal the readily polymerisable hexahydrofluorene, along with traces of bases and phenols, these two last being primary products of low temperature distillation. More recently Pictet, Ramseyer, and

Kaiser (Comptes rend., 1916, 163, 358; this J., 1916, 1145) have extracted from five tons of coal, 0.25% of tar which is closely identical in many of its components with that obtained in quantity from the same coal on distillation at 450° C.

Coal is therefore to be regarded as a mixture of substances of vegetable origin, which have undergone change as the result of bacterial decay, pressure and heat. The original main components, the cellulose and the sap, have both suffered change as the result of the action of these agencies but not to such an extent as to render impossible their identification and separation. Preliminary loosening of the coal substance with pyridine and a final extraction with chloroform has led to the separation of these two portions, the degraded cellulose being the insoluble component, the sap the soluble one (Clark, Wheeler, and Platt, Chem. Soc. Trans., 1913, 103, 1713; this J., 1913, 969). Separate destructive distillation of these shows that the cellulose portion yields phenols, while the sap yields what is virtually petroleum (Jones and Wheeler, Chem. Soc. Trans., 1915, 107, 1318; this J., 1915, 1013). These combined distillates, as obtained from the unresolved coal by distillation *in vacuo* below 450° C., constituted a tar of low specific gravity (0.967—0.999¹⁵). This tar was 61% of the weight of the coal. That portion of it, about one-half, which distilled below 300° C. at ordinary pressure contained: (1) unsaturated hydrocarbons (40—15%); (2) naphthenes; (3) liquid paraffins—the two last-named being about 40% of the oil, with the naphthenes predominating; (4) phenols, chiefly cresols and xylenols (12—15%); (5) aromatic compounds, which, on account of the stability of their picrates to water, were considered to be homologues of naphthalene; (6) pyridine bases, in traces; and (7) traces of a solid paraffin, C₂₇H₅₆. Benzene and its homologues were absent, as were also naphthalene, anthracene, phenanthrene, and solid aromatic bodies generally. The aqueous distillate was strongly acid, and was found to contain hydrochloric acid, with which traces of ammonia were combined (Jones and Wheeler, Chem. Soc. Trans., 1914, 105, 140; this J., 1914, 192). It seemed a matter of interest to investigate the thermal decomposition of this tar, and, with Dr. Wheeler's concurrence, the author undertook this investigation independently. The first experiment carried out was the decomposition of the tar at 650° C. with the object of obtaining the liquid products of decomposition. The tar taken had specific gravity 0.967¹⁵ and contained carbon 86.32%, hydrogen 9.53% (C+H=95.85). It was allowed to flow over coke packed in a vertical tube of hard glass, which was heated in an electric furnace. The temperature was registered by means of a platinum-platinum-rhodium thermocouple, the junction of which was inserted in the hottest part of the furnace. The length of the heated zone was 30 cm., and the gas capacity of the heated zone of the decomposition tube was 30 c.c. The temperature of decomposition (650° C.) was kept fairly constant within about 6° C. The liquid was run in at the rate of about 5 c.c. per hour. Gas was formed to the extent of 220 c.c. per gram of tar taken. The first receiver, which was air cooled, was fitted vertically below the decomposition tube, so that the heavier liquid products of decomposition ran directly into it. The second receiver was cooled in a mixture of solid carbon dioxide and ether contained in a Dewar vessel. The permanent gases were allowed to escape. The tar collected in the first receiver was 55% of the weight of the original tar. It had specific gravity=1.013¹⁵, carbon 88.51, hydrogen 7.18%. It contained a little water in suspension. It began to boil at 128° C., and distilled 19% at 200°, 37% at 250° C., and 50% at 300° C.

The distillate coming over below 300° C. was washed with caustic soda to remove phenols, and with dilute sulphuric acid to remove bases. The separate fractions had the following characteristics:—

	Fraction I.	Fraction II.	Fraction III.
Range of boiling point	110—180°	180—260°	260—300°
Specific gravity	0.8645	0.9093	1.000
Carbon	90.55	90.63	91.36
Hydrogen	9.04	9.11	7.52
C+H	99.59	99.74	98.88

If these figures be contrasted, so far as is possible, with those given by the original tar oils, the increase in specific gravities and carbon content are at once apparent, even when the fractions from the new tar are of lower boiling range than those from the original.

Low temperature tar oils.

	Fraction I.	Fraction II.	Fraction III.	Fraction IV.
Boiling range	160—200°	200—250°	250—275°	275—300°
Specific gravity	0.8045	0.8556	0.8903	0.9278
Carbon	86.28	87.88	88.13	88.21
Hydrogen	13.11	11.65	11.09	10.36
C+H	99.39	99.53	99.22	98.60

From the observation that oxygen is absent from the neutral oil fractions obtained after decomposition it follows that cumarone, C₉H₆O, and its homologues are also absent. As their absence from low temperature tar has been similarly demonstrated, it must be presumed that this substance is formed at higher temperatures, either synthetically or by direct distillation from the coal.

The increases in specific gravity and in carbon content, alluded to above, are due to two causes: increased aromatic formation, and increased olefinic linkage. The latter was the predominant factor, though it was difficult to distinguish accurately and quantitatively between the two (cf. Egloff and Twomey, Met. and Chem. Eng., 1916, 14, 247; this J., 1916, 411), the difficulty being accentuated by the smallness of the amounts available for examination. A further difficulty was occasioned by the fact that aromatic substances were present in the original tar, and these passed through the heated zone apparently unchanged. A small quantity of aromatic substances of specific gravity 0.89 (determined by flotation) was distilled from a strong sulphuric acid wash of the lower fractions, and the aromatic substances originally present were recovered from the higher boiling portions. No solid aromatic substances such as naphthalene or anthracene could be detected in the tar. A study of the gases formed at various temperatures was therefore begun. The only aromatic substance which could possibly affect the gas analyses in any way was benzene, and that only to a limited extent owing to its low vapour tension, and to its comparative absence at the lower temperatures of decomposition. The gas absorbents used were: (1) Sulphuric acid of 96% strength. This removes olefines containing from 3 to 6 carbon atoms in the molecule, thus discriminating between ethylene and the higher members of the series. (2) Ammoniacal silver chloride for acetylene. (3) Bromine in potassium bromide solution for ethylene. (4) Freshly-prepared ammoniacal cuprous chloride for carbon monoxide. Hydrogen was estimated by removing

it with "burnt" palladium at 96° C. and the remaining methane and ethane were determined by explosion.

Investigation was first made of the gases which were boiled off at a temperature range of -80° C. to +35° C. from the ether-CO₂ cooled receiver which served as the second condenser in the experiment carried out at 650° C. as described above. The gases so obtained were found to contain paraffins 21.1% (C₂H₆ 11.8%, C₃H₈ 10.3%), ethylene 5.3%, higher olefines 72.6%. (Gases absorbed by strong sulphuric acid, consisting of olefines containing more than two carbon atoms, are described throughout this paper as "higher olefines.")

The marked preponderance of the olefines over the saturated hydrocarbons is very noticeable, and is in striking contrast to the corresponding gas fraction obtained direct from coal at 450°, and which was found to contain total olefines 23.5% and paraffins 75.1% (Jones and Wheeler, *loc. cit.*). The higher percentage of olefines at this stage was also observed in the liquid fraction from which they had been distilled (b.pt. 35°—120° C.), which appeared to contain over 60% of olefinic substances.

It was then decided to decompose small quantities of the tar at successive temperature increments of 50° C., beginning at 550° C., the lowest temperature at which such decomposition was rapid enough to be conveniently studied under the same conditions as held at higher temperatures. The method adopted was the simple one of distilling a small quantity of the substance over heated porous porcelain in an atmosphere of carbon dioxide, and finally sweeping out the gaseous products of decomposition with carbon dioxide and collecting them over potash in a nitrometer. About 0.1 grm. of substance was placed in a small porcelain boat, which was inserted in the back end of the hard glass decomposition tube (a quartz tube was used at 800°), heated in an electric furnace 30 cm. long and fixed horizontally. Backward diffusion of vapours was prevented as far as possible by the insertion of a plug of glass wool at the back of the boat. After the boat had been placed in position and all air driven out by carbon dioxide, the current of the latter was shut off, and the nitrometer filled with potash. The tube was then moved along so as to bring the boat into the hot zone of the furnace. The tar was then distilled and decomposed. The results obtained in the form of percentages calculated as "nitrogen-free" are set forth in the following table:—

Temp.	Higher olefines.	C ₂ H ₂ .	C ₂ H ₄ .	H ₂ .	CH ₄ .	C ₂ H ₆ .
(2) 550° C.	21.7	0.7	10.4	29.4	19.6	18.2
(3) 600° C.	12.5	1.3	7.4	33.6	33.9	11.3
(4) 650° C.	11.4	0.9	9.3	27.4	39.0	12.0
(5) 700° C.	8.2	1.3	16.1	28.2	43.8	2.4
(6) 750° C.	0.7	1.2	7.6	33.2	56.1	1.2
(7) 800° C.	1.0	1.3	4.0	60.7	33.0	—

As carbon monoxide is formed as the result of the action of nascent hydrogen on carbon dioxide at the given temperatures, no column is assigned to it in the above table, and it is included in the hydrogen. A separate experiment showed that when the tar was decomposed *in vacuo* at 550° C., only 0.6% of carbon monoxide was found in the resulting gas. Carbon monoxide is found in quantity in coal gas, but it proceeds largely from the insoluble portion of the coal, and to a much less extent from the soluble portion from which the bulk of the tar is derived (Clark and Wheeler, Chem. Soc. Trans., 1913, 103, 1704; this J., 1913, 969). The figures given represent the percentages of the various components in the gas mixture and not the absolute amounts.

No examination was made of the liquids. It was observed, however, that naphthalene was deposited in the front end of the tube at 750° C., though not below this temperature. It will be noticed on studying the curves, that ethylene

increases to a maximum at 700° C., and then falls; acetylene is uniformly low and almost negligible; the higher olefines fall from a maximum at 550° almost to zero at 750° C.; hydrogen averages about 30% till 750° C. is passed, when the curve becomes steep; methane rises rapidly to 750° and then falls.

In order to avoid confusion with the curves for ethylene and the higher olefines, the curve for ethane is indicated by dotted lines. It shows a fairly steady decline.

No simple explanation is vouchsafed for the contour of the ethylene curve. The rise may perhaps be explained in part by the fall in the ethane, and also by the direct formation of ethylene as a primary decomposition product of the various tar components, saturated and unsaturated. Analyses (8), (9), and (10) show that from 20 to 30% of ethylene was present in the gases obtained by rapidly decomposing various oil fractions at 650° C. The low percentages of acetylene call for remark, in view of the important rôle which has been assigned to this compound as a participant in coal tar formation. If, as is still held by some, notably R. Meyer (Ber., 1912, 45, 1609; this J., 1912, 633), acetylene plays a prominent part in coal tar formation, it should be present in much larger quantities than are here indicated. Bone and Coward have shown (Chem. Soc. Trans., 1908, 93, 1197; this J. 1908, 886) that the velocity of polymerisation of this gas when formed by the thermal decomposition of ethylene at 570°—580° is not so rapid as not to allow of its accumulation to the extent of from 6 to 7%, at which value it remained fairly constant after prolonged heating.

The curve for the higher olefines differs considerably from that of ethylene in that it exhibits a steady decline from 550° to 750° C. The higher olefines practically vanish at this latter temperature, and their disappearance synchronises with the appearance of naphthalene, and with the commencement of a marked increase in the

hydrogen. This fall in the curve finds a counterpart in the results of Egloff and Twomey obtained by them when decomposing Pennsylvania petroleum (Met. and Chem. Eng., 1916, 14, 247; this J., 1916, 411). They observed, particularly in the case of the low boiling fractions, that the liquid olefines were at a maximum at 550° C., and that there was a more or less steady fall in the curve from 44% at that temperature to 5% at 800° C. Their curve does not, however, coincide with the gas curve shown here, in that it shows there is still 25% of liquid olefines remaining at 700° C. and 15% at 750° C.

Ordinary coal tar oils, particularly the lower fractions, contain very little olefines. In ordinary crude benzol from coal tar, the olefines present,

cussed below, the process is represented by the simple scheme:—

Low temperature tar → Higher olefines → High temperature tar.
(liquid and gaseous)

The mechanism of the condensation has not yet been investigated. The suggestion that naphthenes are intermediate products in the condensation cannot be upheld in view of the observation made by the author that these substances break down at 500° C. (Chem. Soc. Trans., 1915, 107, 1582; this J., 1915, 1239).

The formation of gaseous olefines is more marked in the case of certain tar-oil fractions than of the tar itself, as can be seen from the following table which gives results obtained at 650° C.

Fraction.		Higher olefines.	C ₃ H ₄ (+ C ₂ H ₂)	H ₂	CH ₄	C ₂ H ₆	Total "unsaturated."
Sp. gr.	R.pt.						
(8) 0.69	38–100° (olefine-free)	29.9	20.6	13.7	19.6	16.2	50.5
(9) 0.784	200–250° (olefine-free)	26.8	23.8	12.6	21.7	9.1	56.6
(10) 0.855	200–250°	24.2	22.6	21.6	25.5	6.1	46.8

which are removed as "acid tar" with strong sulphuric acid, amount to about from 2% to 1% of the whole. A fraction of similar range of boiling obtained from low temperature tar lost over 50% of its volume as "acid tar" on washing with strong sulphuric acid.

The higher olefine curves differ from those of Zanetti (J. Ind. Eng. Chem., 1916, 8, 671; this J., 1916, 957), who observed that a propane-butane mixture yielded a maximum of "unsaturateds" at 750° C. Zanetti, however, makes no distinction between ethylene and other olefines, and the high percentage of "unsaturateds" probably consists very largely of the former. It is to be observed that Zanetti comments on a rapid increase in hydrogen and aromatic substances immediately above 750° C.

Staudinger's work on di-olefines with conjugated double linkings appears to have a distinct bearing on the results already recorded (Staudinger, Endle, and Herold, Ber., 1913, 46, 2466). It was observed that di-olefines of this type yielded aromatic substances in quantity when heated to 800° C. Isoprene first gave aromatic substances in quantity at 750° C. along with unsaturated substances. At 800° C. the aromatic substances had increased, while unsaturated had almost disappeared.

Staudinger further identified butadiene, the simplest di-olefine of this type, in gas distilled from coal *in vacuo*. Its formation from naphthenes has been demonstrated (Engler and Staudinger, Ber., 1913, 46, 2466; Ger. Pat. 241,895), as it has also from many olefines and saturated hydrocarbons (Ostrowski, J. Russ. Phys. Chem. Soc., 1915, 47, 1917–1978; this J., 1916, 380). It also appears prominently in various petroleum vapours as the result of decomposition at 700° C. (Lomax, Dunstan, and Thole, Chem. Trade J., 1916, 59, 458; Engineering, 1916, 102, 511).

These combined results tend to show that in coal tar formation the bulk of the high temperature tar is formed by the decomposition of the low temperature tar into olefines, and the condensation of these at 700° C. and upwards to aromatic substances. It is highly probable that a necessary transition stage is the formation and condensation of olefines containing the stable conjugated double linkage—CH=CH:CH=CH—. Polynuclear aromatic substances are formed at 750° C. and upwards subsequent to the disappearance of the olefines. With certain reservations which are dis-

Certain modifications relating to the phenols, benzenoid substances, and pitch must be made in the above scheme. The phenols of high temperature tar must be regarded as having been formed with certain changes from the phenols of low temperature tar.* Much of the high temperature pitch is formed by partial carbonisation of the low temperature pitch.

Benzenoid substances, in addition to being formed synthetically from olefines, are also formed to a limited extent by the elimination of six hydrogen atoms from the corresponding naphthenes. This change, however, only takes place to a very limited extent. Naphthenes of the cyclohexane series do not break down entirely in this way, but also undergo scission of the ring, with formation of olefines, including butadiene, and paraffins. The author has shown that both these processes of breakdown take place at 550° C. (Chem. Soc. Trans., 1915, 107, 1582). This is also manifest in analysis (9), where the fraction concerned consisted largely of naphthenes. If all the benzene, toluene, and their homologues found in ordinary coal tar were obtained directly from naphthenes by simple elimination of hydrogen, it follows that at temperatures not much above 550° C. coal would yield the maximum possible amounts of these substances. It is well known, however, that when coal is distilled at dull redness only small quantities of benzenoid hydrocarbons are found in the tar.

It might be argued that the naphthalene deposited at 750° C. may have been derived from the methylnaphthalenes originally present by a form of decomposition analogous to that by which xylene successively yields toluene and benzene (Rittman, Byron, and Egloff, J. Ind. Eng. Chem., 1915, 7, 1019; Egloff and Twomey, J. Phys. Chem., 1916, 20, 115; this J., 1916, 105, 296). The presence of naphthalene cannot, however, be adequately accounted for in this way. A tar oil fraction from which methylnaphthalenes had been removed with picric acid was thermally decomposed at 750° C. and it was observed that naphthalene was deposited in quantity at the front of the tube. The gas analysis (11), it is to be observed, shows very little higher olefines.

* Pictet and Bouvier (Ber., 1913, 46, 3342) found no phenols in a vacuum tar freshly distilled from certain French coals. On standing, however, phenols were formed, apparently from alcoholic bodies present (Pictet, Rev. Gén. des Sciences, Oct. 30, 1916, 7).

	Higher olefines.	C ₂ H ₄ .	H ₂ .	CH ₄ .
(11)	1.9	10.9	18.3	68.9

An explanation of the formation of hydrogen at intermediate temperatures has been given above in discussing the thermal decomposition of the naphthenes. Some hydrogen may also have been formed to a lesser extent from other hydrocarbons, notably ethane. Its increased formation at temperatures above 750° with the concomitant appearance of polynuclear aromatic substances has not been explained. Similar observations of increased hydrogen formation have been recorded by Zanetti with a propane-butane mixture (*loc. cit.*) and by Burgess and Wheeler with bituminous coal and with anthracite (Chem. Soc. Trans. 1910, 97, 1917; this J., 1910, 1291). In all three cases it was observed that the hydrogen curve became steep above 750° C., and Zanetti also noticed increased aromatic formation at the same temperature.

As very few measurements have been recorded of the conditions of thermal decomposition of individual substances at these temperatures, it is not an easy matter to explain the above coincidences. Smith and Lewcock have observed (Chem. Soc. Trans., 1912, 101, 1453; this J., 1912, 807) that the combination of two molecules of benzene to diphenyl with elimination of hydrogen takes place slowly at 655° C., and rapidly at 720° C. With increased concentration of benzenoid substances some combination of this kind must inevitably occur. Diphenyl is known to be a constituent of coal tar. The observation of Burgess and Wheeler concerning anthracite shows that the increased formation of hydrogen is not dependent upon changes of such a kind as can only take place in the vapour phase. It could not for instance be asserted, if regard is to be had for these coincidences, that the increased hydrogen is due to the prior disappearance of olefines, which may hitherto have combined with and retained it. The change which produces this hydrogen is evidently of such a kind as takes place between large molecules and also intramolecularly. The increased production of hydrogen must probably therefore be attributed to the union of aromatic molecules, and to the intramolecular closing up of side chains and rings of these to form new rings. Simple examples of these changes are the formation of diphenyl from benzene already mentioned, and that of naphthalene from phenylbutylene and of phenanthrene from stilbene and *o*-ditolyl.

The increased hydrogen formation in tar and petroleum fractions is thus necessarily concomitant with the formation of polynuclear aromatic substances, while the similar hydrogen formation in coal marks the beginning of the rapid conversion of the coal to polynuclear molecules of indefinite dimensions, a process which culminates in their coalescence to the aromatic molecule of carbon.

The curves for ethane and methane call for little comment. Bone and Coward (*loc. cit.*) have shown that the former decomposes rapidly at

675° C., and that at 810° C. only 17.9% remained after heating for one minute. The disappearance of ethane with rise of temperature was therefore to be anticipated. It is possible that paraffins higher in the series than ethane are present at lower temperatures. These would appear in the analyses as ethane, and the early rapid fall in the curve may be due in part to their decomposition.

Methane is a general product of most thermal decompositions, even of such substances as carbohydrates where its formation might be least expected. The observed rise in the methane curve is in accordance with this and with its known stability.

SUMMARY.

(1) Ordinary coal tar is formed from coal at high temperatures chiefly as the result of the decomposition of a tar previously formed at low temperatures.

(2) The mechanism of this process consists essentially in the decomposition of the naphthenes, paraffins, and unsaturated hydrocarbons present in the low temperature tar to form olefines of varying carbon content which condense at higher temperatures to aromatic substances.

(3) The higher (gaseous) olefines are at a maximum at 550° C., the curve descending to a minimum at 750° C., when they virtually disappear. Their disappearance at 750° C. synchronises with the appearance of naphthalene, and immediately precedes a rapid increase in the evolution of hydrogen.

(4) Hydrogen is formed at middle temperatures chiefly as the result of the decomposition of naphthenes. The increase at higher temperatures must probably be attributed to the union of aromatic molecules and to intramolecular ring closing.

(5) Phenols are primary products of coal distillation (*cf.*, however, Pietet, *loc. cit.*).

(6) Benzene and its homologues are chiefly formed as the result of olefinic condensation. To some extent they are secondary products of coal distillation, having been formed by the thermal dehydrogenation of the corresponding naphthenes.

(7) Acetylene plays an insignificant part in coal tar formation.

New York Section.

Meeting held at Rumford Hall, Chemists' Building, on Friday, November 24th, 1916.

MR. JEROME ALEXANDER IN THE CHAIR.

THE IMPORTANCE OF "IMPURITIES."

BY JEROME ALEXANDER.

Many of the discoveries and improvements of chemical science have been due to the recognition of the importance of impurities. Although it has long been known that chemical and physical changes can be brought about or influenced by extremely minute quantities of substances which exercise disproportionately great effects, it is only within comparatively recent years that the widespread occurrence and technical importance of these phenomena have been recognized. Thus, for example, a minute quantity of platinum black, one part to a million according to Bredig and von Berneck,* is able to decompose hydrogen peroxide, and as an extreme case, Brode states that one gram-molecule of molybdic acid in 31,000,000 litres has a detectable catalytic effect upon the reaction between hydriodic acid and hydrogen peroxide. The effect of an infusion of straw or

* Z. Physik. Chem., 1899, 31, 353; see also this J., 1901, 376.

similar substances in rendering clay plastic may not have been known as such to the Egyptians; but they certainly knew that bricks could not be made without straw. Coming to more recent times, let us consider a few cases where so-called impurities are of great technical importance.

Auer von Welsbach's experiments to produce a satisfactory incandescence gas mantle had been unsuccessful, when he once more took up the investigation of thoria, which had in his preliminary work given a good though transitory effect. In the attempt to prepare pure thoria the surprising discovery was made that the purer the thoria preparations, the lower their illuminating power, and the identification and use of cerium as the light-giving impurity brought success to the incandescence gas mantle industry.

The importance of impurities is so well recognized in the iron and steel industry, that its products are made according to specifications limiting some of them to the third decimal place. Even the impurities in alloying metals must be considered, for the early attempts to produce a workable nickel steel failed because of such impurities as copper, arsenic, and sulphur which existed in the commercial nickel of that day.

H. A. Bernthsen, in his address on the production of synthetic ammonia by the Haber process*, pointed out that sulphur, selenium, tellurium, phosphorus, arsenic, boron, or the compounds of these elements such as the hydrides, and also many carbon compounds and certain metals of low melting point such as lead, bismuth, and tin, may all act as poisons to the catalyst. Sulphur dioxide is very poisonous. Bernthsen says: "Extremely minute quantities of these bodies, which are almost always present even in the purest commercial products or in so-called pure gases, suffice to render the catalysts absolutely inactive or at least to diminish their action very seriously. Thus iron, for example, prepared from ordinary iron oxide with a content of one per thousand of sodium sulphate is, as a rule, inactive. Iron containing 0.1% of sulphur is generally quite useless, and even with 0.01% is of very little use, although in appearance and when examined with ordinary physical and chemical methods no difference at all can be detected as compared with pure iron.

"The recognition of these facts gave rise to two problems: (A) The preparation of contact masses free from poison or the removal of such poisons from them, and (B) freeing the gases to be acted upon catalytically from all contact poisons. A trace of sulphur, one part per million, in the gas mixture, can under certain conditions be injurious, so that even electrolytically prepared hydrogen must generally be further specially purified.

"A painstaking study, for which we are indebted principally to Dr. A. Mittasch and which involved literally many thousands of experiments, has afforded an insight into the importance of substances of the most varied nature as promoters and poisons, and thus a sure foundation has been prepared for a reliable continuous manufacture with a good yield of ammonia."

The catalytic nickel used in the hydrogenation of oils is so sensitive to impurities that Paul Sabatier in his paper on "Hydrogenation by Catalysis" states that small traces of bromine in the air of the laboratory rendered it impossible to hydrogenate phenol which had stood there in an open flask. Benzol which could not be freed from thiophen, could not be converted into cyclohexane.

With some substances the escape of mere traces must be prevented. Thus, in the manufacture of sulphonal there is produced a mercaptan, the odour of which is described as appalling, and so powerful

that ~~xxxxxxxx~~ mgrm. may be recognised. Obviously not much can be allowed to escape.

An interesting demonstration of the importance and efficiency of apparently negligible traces is given by Dr. W. R. Whitney in his recent Willard Gibbs Medal Address (J. Ind. Eng. Chem., 8, 563), in which he states:—"I remember also that after we had tried to increase the resistance of our early tungsten filaments by introduction of rare oxides and other material which we hoped would remain in the filament when hot, and had seen them distil out at the temperature of operation, someone suggested adding traces of such oxides for the purpose of increasing the life of the filament. It seemed a futile experiment, but the traces served the new purpose, while greater quantities had failed."

Through the kindness of Dr. G. W. Thompson, of the National Lead Company, I am able to show two corroded lead buckles which exhibit the effect of impurities in metallic lead upon the white lead made from it. One was made from lead containing only 0.01% of silver, and shows a very deep pink colour, probably due to silver sulphide. The other was made from lead containing 0.02% of copper, and shows a marked green coloration.

In the case of copper, small amounts of arsenic seriously affect the conductivity. Thus W. Hampe (Ch. m.-Zeit., 1892, 16, 726-728; this J., 1892, 1014) reports that if the conductivity of pure copper be rated at 100, the conductivity of copper containing 0.246% of arsenic falls to 61.05. E. S. Sperry (Trans. Amer. Inst. Min. Eng., Feb., 1898; this J., 1898, 582) has pointed out the injurious effects of antimony and bismuth in copper upon brass made with it. He states that brass containing 0.006% of antimony can be rolled without cracking, but when the percentage reaches 0.02 the fracture indicates the presence of the antimony. Sperry also found bismuth to be very objectionable (Eng. and Min. J., 1898, 66, 519; this J., 1899, 47, because it renders brass hot-short, cold-short, and determines actual or "latent" firecracks. He therefore advises that high brass intended for cold rolling should not contain over 0.01% of bismuth. Cadmium, which frequently occurs as an impurity in zinc, also injuriously affects brass. On the other hand, I am informed that a small percentage of lead in brass makes it machine well. But quite the contrary is the case with gold, which is rendered brittle by 0.05% of lead.

In the refining or deposition of metals by electrolytic methods there are numerous instances published in the technical and patent literature dealing with the beneficial or detrimental effects of small quantities of previously neglected "impurities," some accidentally, but some intentionally added. Sulphates interfere with the electrolysis of magnesium chloride and with the electrolytic production of chlorates. In electroplating with gold, a little copper gives a red shade and a little silver gives a greenish shade. In fact, quite a variety of colours may be produced by the judicious introduction of suitable impurities. The work of Anson Betts has demonstrated the effect of tannin and similar substances which behave like protective colloids, upon the electro-deposition of lead. The effect of protectors can be exhibited by dividing a solution of lead nitrate between two beakers, adding some gum arabic solution to one, and then inserting a strip of zinc into each beaker. A brilliant crystalline lead tree deposits on the strip in the solution without the gum, whereas the other deposit appears blackish and amorphous.

The following are a few scattered instances. In the manufacture of dry batteries, traces of iron in the pyrolusite and of copper in the sal ammoniac have been found to be detrimental. Traces of arsenic in the hydrogen used by lead burners prevent the formation of a proper joint. Nitric acid carboys which had been used in a felt factory

*Eighth Int. Congr. Appl. Chem., New York, 1912; this J., 1912, 982.

to make mercuric nitrate for carroting, retained enough mercury to cause serious trouble when they were refilled and sent to another plant. Traces of copper or iron in tanning materials are inimical to the production of white leather. As little as one part of sulphur per million in coconut oil has a deleterious effect on the soap made from it. Water and air in liquid ammonia may accumulate and cause trouble with the refrigerating machinery. Iodine, fluorine, and arsenic are poisons prohibited in foods; yet physiological chemists state that certain small quantities of these substances which we unwittingly take in our food, are essential to our bodily well-being.

In the brewing industry, many peculiar facts, long known, have been traced to the presence of disregarded impurities; for instance, "Burton water" is supposed to owe its advantageous properties to traces of calcium salts, and patents have been granted for "Burtonizing" brewing water. The outbreak of "beer-poisoning" in Manchester, England, in 1900, was traced to arsenic in the mineral acid used in making brewing sugar. Where would be our present knowledge of radium and radioactivity, had not the Curies traced and isolated the potent impurities of pitch-blende?

The importance of traces of manganese in plant growth has been pointed out by Gabriel Bertrand who found that one part of this metal in ten million exercised a noticeable favourable effect upon the growth of *Aspergillus niger*, both the ash and the weight of the plant being increased. On the other hand, Raulins in 1870, experimenting with the same organism, found that one part of silver nitrate in 1,600,000 prevents growth. When growth was attempted in a silver cup, vegetation did not even begin. Duclaux, commenting upon this, remarked that "it is almost impossible to detect chemically any dissolution of silver into the liquid. But the fungus proves it by dying."

This naturally leads us to a consideration of the influence exerted upon physiological changes by the presence of substances that in the past might have been regarded as unimportant impurities. Take the enzymes for example, the distribution and importance of which are only now being recognised. With the aid of enzymes changes take place with comparative ease, which ordinarily require quite severe treatment with inorganic chemicals. Thus, according to E. F. Armstrong, 2-N hydrochloric acid required about five weeks at 35° C. to produce the same degree of hydrolysis as was produced by a certain preparation of lactase in one hour. Although the preparations of enzymes actually used in experiments contain only small percentages of the active enzymes themselves, some indication of their enormous efficiency may be gained from the statement of O'Sullivan and Tompson that invertase can hydrolyze 200,000 times its weight of sucrose, and the report of Hammarsten that one part of rennet can clot 400,000 times its weight of caseinogen in milk. The great efficiency of the enzymes becomes comprehensible upon ultramicroscopic examination, which reveals the continuous kinetic activity of their multitudinous particles. I have seen the particles of taka-diastase concentrated about a starch granule, probably by adsorption, practically gnaw holes in it. It is difficult to say where physical action ends and chemical action begins, for there is no sharp line of demarcation between the two.

In conclusion, I must deprecate the tendency of some scientifically educated people to dismiss in a cavalier manner observations coming to them from any source, no matter how humble. If we cannot give a scientific reason for a fact, we must work to enlarge our fund of scientific knowledge, not close our eyes to the truth, because it does not fit in with present-day theories. Most of us have smiled at the fetish-like prescriptions of the

Egyptians and Chinese, which include toads, caterpillars, and the like, not knowing that toads had long formed the basis of a folk remedy among Western nations and our own American colonists, and had even been used by the medical profession. Last year, however, Prof. John J. Abel announced in "Science" that he had isolated from the skin of *Bufo aqua*, a tropical toad, considerable quantities of that powerful drug adrenalin or epinephrin, and also a crystalline substance which he calls "bufagin" to which he says the skin owes its curative power in dropsy.

The practical housewife has known for centuries that if the white of an egg is overbeaten it runs to water; but just recently our colloid chemists have talked of the coagulation of colloids by mechanical agitation. Many decades ago, the British explorer, Captain Speke, reported the widespread belief among the African natives that the sleeping sickness was associated with the coming of the tsetse fly, but this was regarded as a superstition rather than a fact. Tardy science has since proved it to be true and has greatly extended our knowledge and control of the tiny insect carriers of disease, heretofore neglected as "unimportant impurities."

Experiment is the basis of all knowledge. But experiment must be accompanied by exact observation and correct deduction if we would find truth. In our search, let us not neglect any source or factor, no matter how lowly or insignificant it may seem, for the very thing we cast aside as unimportant or negligible may be the key to the door we seek to open.

SOME PRESENT-DAY TECHNOCHEMICAL PROBLEMS.

BY DR. RAYMOND F. BACON.*

Theodore N. Vail, the distinguished organizer of the greatest telephone system in the world, has well expressed a recent industrial recognition:

"Research, investigation, experiment, comprehensive and thorough, are now necessary to hold any position in any industrial or utility enterprise."

Mr. Vail attributes the success of his company—the nervous system of our economic and social structure—to the centralised, co-ordinated work of operation with research. Transportation, the circulatory system of the world, owes a similar debt to scientific investigation, for its development has resulted entirely from industrial growth, for which chemical inquiry is so largely responsible. It is now generally conceded that research and progress are synonymous as applied to manufacturing.†

The recent impetus imparted to the investigational activity in American chemical manufacturing has materially altered the traditional policy of industrial secrecy.‡ This change in attitude, the direct product of the appreciation of urgent action in industrial research, has been long desired by our universities, and it will undoubtedly result in the extension of the practice of referring certain of the problems of industry to university laboratories for study. Many of the numerous problems of chemical manufacturing could be advantageously attacked outside of the plants; but some

* On May 14th, 1915, I addressed the Chicago Section of the American Chemical Society on "Some Problems of Chemical Industry," and the discourse was duly published, in condensed form, in *J. Ind. Eng. Chem.*, 7 (1915), 535. However, a number of omissions occurred in that brief report, and, at the request of my colleagues, I have endeavoured to supply, principally for the research workers in our universities, the additions necessitated for completion of the presentation. The present contribution is therefore supplemental to the paper cited.

† On this relation, see Bacon, *Sci. Am. Suppl.*, 1915, No. 2087, 334.

‡ For an illustration, see the reports of the Industrial Conferences at the 53rd Meeting of the American Chemical Society (*J. Ind. Eng. Chem.*, 8 (1916), 947 *et seq.*).

central organisation, similar to the Committee on Research in Educational Institutions of the National Research Council, is needed for securing and properly distributing those problems which are pressing. It is clear, however, that stable relations between the universities and industrialists will be worth while only if some mutual benefits can accrue therefrom. This co-operation can therefore be most satisfactorily promoted by actively demonstrating the advantages of the exchange or interchange of subjects for research, which primarily presupposes a reasonable freedom from the concealment of knowledge which tenaciously adheres to all industrial research.

I shall now pass rapidly over a few of the many important problems of manufacture,* for the most part in the traditional industries—problems that a few years ago were either not given any consideration or were unknown, but which are now the subjects of considerable contemporary inquiry and even anxiety.

Some present-day metallurgical problems.

A metallurgical problem which invites the investment of research with peculiar force, is the concentration of the so-called brown-ore of Virginia, Tennessee, Kentucky, Georgia, Alabama, and Texas. Calined brown-ore carrying more than 50% of iron is readily marketable and it is said that processes of the type of the Goltra method may be profitably applied not only to these deposits but also to brown-ore "banks" which cannot be worked by old methods of preparation. Other iron-ore problems are the economic utilization of the aluminous ores of Tennessee and of the siliceous potash-bearing ores (gray iron ores) which occur in other southern States.

In blast-furnace practice, there is needed some method of increasing the basicity of the slag without increasing its temperature; very little information is available regarding the amount of sulphur which can be expelled with the top gases; the control of manganese is comparatively incomplete; little is known of the general subject of the effects of variations in the carbon contents of the different kinds of iron, and consequently we are unacquainted in detail with methods for the systematic control of carbon; and there is a lack of experimental knowledge relating to the action of a considerable percentage of vanadium in the blast-furnace charge. Reference may also be made here to the problem presented in the production of ferro-vanadium alloys directly from iron ores containing vanadium; this is difficult because vanadium goes into slag very readily.

The following are some of the many other problems in siderurgy: the recovery of manganese as an alloy from slags high in manganese; the extension of the commercial uses of open-hearth and converter slags, particularly a broad study of their use in ceramics; the improvement of the quality of cast-iron or pig iron of ordinary coke grade, to make it the equal of higher-priced charcoal iron; the influence of β -iron on the hardening of steel; the relative merits, as regards corrosion, of various iron products, and especially pure iron as compared with ordinary open-hearth and copper-bearing steels;† the cause of internal transverse defects in rails; satisfactory substitutes for imported magnesite as an iron and steel refractory (zirconia is too costly)—this problem actually resolves itself into how to use domestic

magnesite—and for graphite as a foundry facing; the cause of the lack of success in the use of ferro-silicon to replace entirely the ferro-manganese in the deoxidation of steel; and the possibility of recovering by-products from blast-furnace gases, such as compounds from which cyanides might be made.

Mention has been made in several other communications* of certain of the problems encountered in the metallurgy of zinc. The treatment of flotation concentrate is one of the present troubles of the zinc smelter, owing to its great fineness. While the proportion of this grade of ore which the smelter is obtaining is still small, the supply of it is, however, certain to increase. The roasting of ferruginous blende in such a manner as to convert all of the zinc into sulphate and oxide, avoiding the formation of sulphite and ferrite, is another interesting subject for research. Two other problems in this field are the manufacture of retorts of higher tensile strength and greater durability, and the relation of the elements of the ash ingredients of the reduction fuel to the same elements in the ore, having in mind a more satisfactory blending of the ore and the reduction material.

The increasing adaptation of flotation to the treatment of low-grade copper ores has somewhat discouraged the use of leaching methods and accordingly these processes have not made the progress expected; but the field is still open for oxidised ore where flotation has not thus far been successfully applicable. Successful flotation assumes that the copper content of the ore is in the form of disseminated mineral. In the case of ores in which the copper compound is diffused throughout a mass of gangue, such as is undoubtedly true of the copper silicate ores found at Inspiration, it is certain that flotation is out of the question and that some leaching process must be used.

The acidity of the gases from copper and lead smelting works presents a problem which still awaits solution. In electrical precipitation, the treatment of enormous volumes of gases in the smelter flues introduces several problems: in addition to the magnitude thereof, there are the problems connected with the handling of the fumes and dust and their metallurgical treatment. It is, of course, possible at present to separate from certain fumes thousands of tons of arsenic annually and it would probably be feasible to separate an amount of sulphur which would run into hundreds of thousands of tons annually, were there markets for such quantities of these by-products. The problem therefore resolves itself into the establishment of new tonnage uses for arsenic and sulphur.

In the metallurgy of the precious metals, the high price of zinc has stimulated renewed study of electrolytic methods of precipitation (the new plant at Great Falls, Montana, is illustrative of the trend in this direction) and a large amount of experimental work is in progress on the application of the flotation process. In the case of concentrate produced by flotation, the minerals composing the product are substantially the same as those obtained by gravity concentration, consisting of the sulphides and the double sulphide of the heavy metals, and therefore similar difficulties are encountered in their treatment.

Other more familiar metallurgical problems are the prevention of zinc loss in the brass industry, the elimination of arsenic from antimony, and the cheap deoxidation (retrieving) of aluminium remelted from scrap; but after all the conservation of our metals and their protection after they have been manufactured and put into service, holds out most interest.

* In collating these I have drawn from all available sources of information and especially from my experience at the Mellon Institute.

† Because of the immense amount of research which has been carried out on this subject, I have hesitated in citing the above-mentioned problem as unsolved. However, the fact that controversy still prevails places it in that class. Personally I believe that the advocates of the use of copper-bearing steels have much the best of the argument.

* See Bacon, *Science*, N. S., **40** (1914), 877; and *J. Ind. Eng. Chem.*, **7** (1915), 535.

Among the less used metals, the alkaline-earth elements are begging utility. There is no doubt that calcium could be produced economically even by methods now known if it were manufactured on a large scale to fill an extensive demand, but markets therefor must first be established by the discovery of important new uses. Results of commercial significance might be obtained by the investigation of the alloys of calcium and of its application as a chemical purifying agent in melting and casting metals. Calcium has been used in Germany as a substitute for ferro-manganese in the deoxidation of steel. In the cases of barium and strontium, uses could be developed if methods were known by which these metals could be isolated cheaply; while with magnesium an electrolytic method is required which will enable its production for about 25 cents per pound (direct reduction of the oxide, as in the case of alumina, is suggestive). Beryllium is another metal whose properties should receive broad investigation, for at present its known uses do not justify its cost.

The production of boron and ferro-boron of uniform quality requires expert study. Cheap and pure chromium is now unobtainable; the electrolysis of its fused salts is difficult on account of their high melting-points, but perhaps the electrolysis of aqueous solutions of chromium salts could be so controlled that heavy deposits would be produced. Then, too, chromium electroplating is for many purposes superior to nickel, but the technique of constantly producing perfect plating has not been accomplished.

Since there is no lack of raw materials, broad study should be made of the methods for producing pure titanium and zirconium and of their prospective uses. The same statement also applies to molybdenum, although the greatest need of the molybdenum industry at the present time is a more economic utilisation of its sources of raw material: in general, the deposits have been neither properly prospected nor opened up, and then not wisely worked; and loss and waste should be minimised as the result of a careful investigation of crushing and concentrating methods. However, the relatively small tonnage of molybdenum needed at present is a handicap in the exploitation of its ore deposits.

Other problems of industrial inorganic chemistry.

There is real need of extensive experimental research on the chemical character of coal. The knowledge regarding the combustion and distillation of coal is principally empirical, and will of course remain so until a clearer insight is had of the actual nature of the complex compounds contained in the coal substance and of the mechanism of their decomposition by heat. Two very important problems in the preparation of coal for the market have to do with "wastes": the production of an absolutely smokeless fuel in the manufacture of briquettes from anthracite culm; and the utilisation of the high-ash (60–75%), high-sulphur (5–10%) waste from bituminous coal washers.

Many other problems exist in the domain of mineral technology. New uses are desired for tripoli; the Gypsum Industries Association is engaged in furthering the development and advancement of the uses of gypsum; and the employment of slate in the manufacture of blackboards and school "slates" has so decreased that new applications are wanted to replace this loss of market. Then there are the problems in connection with the use of the natural abrasives, emery and corundum; one still hears of the sudden and wide variation in the composition of different shipments; but since the development of high-grade artificial abrasives and the exploitation of

larger corundum deposits in Ontario, no corundum has been produced and only a small quantity of emery has been mined in the United States, and accordingly new uses are being sought for these minerals. The abrasive garnet market is also strictly limited and shows little tendency to extension at present. Reference may be made here to several problems in the technology of fullers' earth, the literature of which is meagre and unsatisfactory. Little is known regarding the qualities of fullers' earth which adapt it to its applications; there is a needless obscurity concerning the changes which it occasions in oils and to which it is itself liable; it is not clear why certain earths possess a tendency to cause spontaneous combustion in the material from the filter presses; and, finally, what is the cause of the malodour which sometimes accompanies the use of a particular earth?

The problem of commercially separating a soluble potassium salt from brine containing sodium chloride, carbonate, and sulphate and other salines remains unsolved; the cleaning and drying of phosphate rock should be done more economically; and the regenerative system of heating has not been profitably applied to the pottery industry. In fact, an attractive variety of problems is found in all sections of the inorganic field, and many—particularly a compact apparatus for generating hydrogen which could be erected on a freight car and easily conveyed about for Governmental purposes; the economic production of nitric acid from ammonia by the catalytic process; the development of a commercial process for manufacturing aluminium nitride; and the direct preparation of hydrated sodium carbonate in a stable, powdered form and of sodium silicate in a readily powdered, solid, soluble form—might be attacked to advantage outside the purlieus of industry.

However, of all the anxious inquiries coming in from our manufacturers, those pertaining to refractories possibly possess the most notable academic interest. What is the exact inversion point of the crystalline form of calcium oxide? Why is the porous form of calcium oxide so much more reactive than the crystalline? What are the physico-chemical properties of ferrous oxide at high temperatures? What are the relations of the inversion points of the iron oxides to one another? Can alumina be satisfactorily made (sintered) into a dense, hard refractory without the aid of a bond, thus obviating the troublesome shrinkage which occurs at temperatures far below the melting-point of alumina? And finally there are the troubles in the case of refractories for open-hearth furnaces. The principal source of difficulty is the slagging tendency of the dust, which is derived partly from the producers and partly from the charges. Perhaps a satisfactory means of suppressing the dust might be devised, but another possible way out of the trouble might consist in replacing the acid bricks of the checkerwork by basic ones. Magnesite and bauxite bricks have been tried, but are liable to shrink; this weakness might be overcome in the case of the bauxite bricks by burning at a sufficiently high temperature and by suitably modifying the texture and composition. Dolomite bricks have not been experimented with.

In fact, it sometimes seems to me that the greatest single problem in chemical technology is the one of refractories. There are many industrial problems that now appear to be impossible of commercial solution, which could be immediately solved, provided we had some ideal refractory substance which would retain its shape and strength at high temperatures and would not be acted upon by the acid or alkaline constituents of a charge or by the gases evolved during the reaction.

Problems of industrial organic chemistry.

The inquiries which come from the domain of organic technology are well illustrative of the opportunities which exist for co-operative research as well as explanatory of the existing anxiety for new ideas in manufacture. More numerous, perhaps, than any others are queries regarding coal products and their manufacture.

In particular, the problems in connection with the by-product coking of coal are of especial importance at the present time. It is generally conceded that "coke breeze" is not being utilized in the most economical manner; new uses should be found for pitch and cumarone resin; the acid tar from the chemical treatment of light oil should be recovered and worked-up; and, for availability in times of peace, there should be accumulated a reserve of knowledge on new uses for benzene and toluene.

The related tar distillation industry presents the following problems*: What is the cause of corrosion in tar stills? Is the present method of separating fractions the best in view of the products required? Uses are also wanted for creosote oil and for lesser known bodies in the distillates; there is required a broad investigation of coal tar pitch to discover ways for rendering it more suitable for replacing natural asphalts; and the methods of testing coal tar products should be standardized. Two questions which have arisen in the manufacture of coal gas are worthy of mention in this place; these are: Have we exhausted the chemical possibilities of by-product or retort coal gas when we have recovered from it the ammonia it contains; and is it feasible to make gasoline from coal gas? This last problem does not appear to me to be commercially practicable in America, but it is under consideration in England and other countries which produce no petroleum.

The numerous problems of the petroleum industry have been considered at length elsewhere,† but reference may be made here to several problems of the Scottish shale oil industry. Much remains to be learned regarding the best conditions for the production of crude shale oil, in particular the form of retort and the temperature of working; 80 to 85% of the raw shale put into the retorts is sent to the waste heaps as spent shale, the utilization of which has not been the subject of sufficiently extensive research; and the refinery tars, now used as fuel, should be investigated with the object of separating commercially valuable substances. These problems are of more than mere passing interest to American chemists on account of the probable early development of certain of our large domestic oil-shale deposits.

The problems of technical phytochemistry are of considerable economic importance. Many of our plants are wasted either because of a lack of knowledge regarding their possibilities or because of a deficiency of interest in their industrial development. The processes for obtaining rubber from guayule sap are unperfected; the method employed for extracting wax from candelilla is crude; algerita and osage orange contain dyestuffs, but have received practically no attention; the commercial possibilities of mesquite seed and wax are unknown, and the same statement applies to the wax or gum from prickly pear cactus; no suitable process is known for degumming ramie fibre and making it suitable for spinning; there is no knowledge of the industrial possibilities of bear grass; the use of rice straw and cotton stalks as paper-making materials requires more study; and the castor bean, sunflower, and camphor tree are well

adapted to the coastal plain of Texas and should constitute the bases of well-established industries.

The cotton industry holds out engaging opportunities for chemical research. The following are some of the problems which confront the planter of cotton: What is the action of various fertilisers on the yield of cotton and on the quality of the fibre produced? Are there available any fertilisers which can be substituted for potash, and, if so, what conditions must be observed in their application to the soil? Can a chemical treatment be devised for destroying the Mexican boll weevil or at least rendering it harmless? And then there are the problems in preventing the production of stained cotton during seasons of excessive rain and in bleaching stained cotton a pure white.

The chemist has been of inestimable value to the wood turpentine industry. In addition to developing processes and designing suitable plants, he has standardized the products, created markets therefor, and found uses for the important by-product, pine oil. However, there are still opportunities for other chemical contributions. Fresh crude turpentine contains normally about 30% of spirits of turpentine, but under the most improved methods of collection and distillation in use at present yields of only 18 to 20% are obtained; this loss of at least one-third of the volatile oil remains to be overcome. The French method of bleaching rosin is slow and otherwise uneconomic, but the chemical methods which have been proposed are unsatisfactory; methods of distillation by the use of superheated steam or vacuum, although apparently desirable, have so far had no altering influence on methods of manufacture; and the disadvantages of wood fibre from turpentine production as a source of pulp remain to be overcome. Notwithstanding its charcoal and bark contents, this fibre is said to produce a satisfactory grade of brown wrapping paper, and there is now some activity in this utilization. The question of substitutes for wood in the manufacture of paper pulp is a pressing one, and any source of relief is gratifying. Perhaps the manufacture of tannic acid extract from palmetto roots and other sources might be made profitable by the production of paper pulp from the fibre residue.

Other problems in the organic branch of chemical industry are the production of a satisfactory butter-substitute from soya-bean oil, the cheap extraction of vitamins from rice hulls and from yeast, the recovery of the wax occurring on the outer surface of the sugar cane, and the economic production of ammonia from sources in the various stages of beet sugar manufacture.

The many opportunities that lie everywhere at hand in this entire field, and particularly in pharmaceutical chemistry, make one frankly consider why expert organic chemists should devote laborious days to preparing some substance of purely academic interest, while there is urgent need for practical working processes for the synthesis of atropine, cocaine, morphine, and quinine. One is reminded of Chesterfield's remark that:—

"Very few people are good economists of their fortune, and still fewer of their time."

when this mismanagement of laboratory resources is further evidenced by citation of the following instances of desired commercial syntheses: formaldehyde, acetic acid, amyl alcohol, tartaric and citric acids, sanguinarine, hydrastine, caffeine, and nicotine.

A favourable occasion for industrial service also exists for the physical chemists of our universities. To mention one illustration from the field of organic chemistry, but little progress has been made in the employment of light in the manufacture of such chemicals as the chlorides of carbon, although photochemistry has developed into an important theoretical branch. Light is a powerful, uncon-

* On other problems of the coal-tar industry, see Bacon, J. Ind. Eng. Chem., 7 (1915), 535.

taminating catalyst for effecting certain chemical reactions, and the white flame arc has opened up many possibilities for controlling and altering oxidation and halogenation processes.

The problems listed above represent only a fraction of those which might be disclosed, but they are illustrative of the opportunities for applying scientific knowledge and investigational methods to the domain of industry. On every side the research men of our universities are needed for the execution of real attainment in the technical world, with its difficulties, wastes, and unexplored lines of manufacturing.

Yorkshire Section.

Meeting held at Leeds on Tuesday, December 5th, 1916.

PROFESSOR J. W. COBB IN THE CHAIR.

THE ESTIMATION OF FREE SULPHURIC, NITRIC, AND PICRIC ACIDS IN THE PRESENCE OF EACH OTHER.

BY F. W. RICHARDSON, F.I.C.

The estimation of sulphuric and nitric acids in the presence of each other presents no special features, and good results may be obtained by well-known methods. The entrance of the third factor, picric acid, creates difficulties. Effluents from picric acid works contain much sulphuric and but little nitric acid, with some picric acid from the wash liquors obtained in the subsequent purifying processes.

In pure solutions picric acid can be very easily estimated. The hydroxyl group gives to the acid the characteristics of quite a strong univalent acid. As the molecular weight of picric acid is 229, 1 c.c. of decinormal alkali is equivalent to 22.9 mgrms. of the acid, an undesirably large figure when the analyst is dealing with minute amounts. In a direct titration of 70 c.c. of an effluent 0.1 c.c. of *N*/10 alkali would represent 2.29 mgrms. or 2.29 grains per gallon of the acid.

I find that while phenolphthalein and methyl orange are good indicators for picric acid, methyl red is more delicate than either. I cannot agree with Minovici and Kollo (see this Journal, 1915, 789) that the use of phenolphthalein requires an excess of alkali to give the end point. Nevertheless these chemists are right in recommending methyl red (*p*-dimethylaminoazobenzene-*o*-carboxylic acid). The end-point is very sharp—the passage from bright red to orange and from orange to pure yellow requires only two drops of decinormal alkali. Iodo-iodate of potassium has been recommended by Sanders (this Journal, 1914, 441):

One molecule of the acid liberates one atom of iodine; therefore the value of 1 c.c. of the thio-sulphate is exactly that of 1 c.c. of decinormal alkali. Leo Schwarz finds that complete reaction only occurs when the solution has been heated for some time in a closed vessel at 100° C.

I have found that 0.5 gm. of picric acid in 100 c.c. of aqueous solution at 15° C. required 13.5 c.c. of *N*/10 thiosulphate, equivalent to only 0.309 gm. or 61.8% of the picric acid taken, and

that the heating process described by Schwarz was necessary. For several reasons the use of iodo-iodate is not to be recommended. The delicacy is no greater than that of methyl red. Heat is required and iodine is volatile. During the heating process free iodine acts upon organic matters present in effluents and introduces a loss, minimising the true proportion of picric acid.

I have tried to utilise the well-known properties of such liquids as benzol and ether for dissolving picric acid, but the results have not been encouraging. Benzol is troublesome on account of the readiness with which it forms emulsions. Ether dissolves so much water that repeated washings with water are necessary, and the peculiar manner in which picric acid passes from ether to aqueous liquid, and *vice versa*, is most disturbing. Moreover, most stream and river waters polluted with picric acid works' effluents contain only very small amounts of the acid itself, say from 1 to 3 grains per gallon. I have therefore abandoned solvent processes and have resorted to colorimetry. Picric acid solutions have the great advantage of being pure yellow, and are easily comparable with the yellow units of Lovibond's tintometer.

One hundred parts of cold water dissolve about 0.6 part of picric acid; this represents about 420 grains of the acid in a gallon of water. A solution containing only 2 parts of the acid in a million parts of water, or $\frac{1}{500}$ grain of the acid in a gallon, can be readily matched as to its yellow colour in a one-inch cell. By using much longer cells quantities as little as $\frac{1}{2500}$ grain of picric acid in a gallon can be matched, and therefore estimated.

It is not very troublesome to work out charts giving the values of thicknesses of picric acid solutions varying from $\frac{1}{8}$ of an inch to 24 inches. In the case of the longer cells I use the special arrangement devised by Mr. Lovibond. To avoid complications I use a glass cell which happens to give 23/25ths of an inch thickness of liquid.

I do not recommend a greater range of units than from 0.5 to 6.0. By dilution or concentration it is very easy to bring the colour depth within these limits. One very necessary caution must be made; the colour depth of picric acid solutions increases very considerably with rising temperature. The following chart shows the increase in colour depths from 0° C. to 60° C., the units increasing from 3.7 to 6.1. From 10° C. to 20° C. the colour increases from 4.05 to 4.5 units.

TABLE A.

Increase of colour-depth on heating a dilute solution of picric acid, using Lovibond's tintometer.

° C.	Yellow units.	° C.	Yellow units.
0	3.7	25	4.7
5	3.85	30	4.9
10	4.05	50	5.7
15	4.30	60	6.1
20	4.50		

I have used 15° C. as the most convenient or the least inconvenient temperature. In the summer months, particularly in July and August, a scale of unit-values for 20° C., or even 25° C., should be used. This scale can be made in a few minutes.

The following table (B) gives the colour-depths of picric acid solutions in a glass cell of $\frac{3}{8}$ inch internal diameter. By a direct reading, obtained in a few moments, the amount of picric acid can be estimated when varying from 1.25 to 60 parts per million or 0.0875 to 4.2 grains per gallon.

TABLE B.

Colour values of dilute solutions of picric acid in a $\frac{3}{16}$ -inch glass cell. (Lovibond's units).

Yellow units.	Grain of picric acid per gall.	Yellow units.	Grain of picric acid per gall.	Yellow units.	Grains of picric acid per gall.
0.3	0.0875	2.1	0.90	3.5	1.61
0.6	0.1750	2.2	0.92	3.6	1.68
0.8	0.2800	2.3	0.95	3.7	1.82
1.0	0.35	2.4	0.98	3.8	1.84
1.1	0.39	2.5	1.05	3.9	1.86
1.2	0.42	2.6	1.09	4.0	1.89
1.3	0.49	2.7	1.12	4.1	2.03
1.4	0.53	2.8	1.19	4.2	2.10
1.5	0.56	2.9	1.33	4.3	2.16
1.6	0.59	3.0	1.37	4.4	2.24
1.7	0.63	3.1	1.40	4.5	2.31
1.8	0.67	3.2	1.43	4.6	2.38
1.9	0.70	3.3	1.47	4.7	2.45
2.0	0.875	3.4	1.54	4.8	2.52

I find that this chart is sufficient for most stream, river, or canal waters containing picric acid effluents. By concentration or dilution to fixed volumes any picric acid solution can readily be brought within this range.

I estimate the nitric acid by phenoldisulphonic acid in the well-known manner with certain modifications, using the table given by Hollings and myself (see this Journal, 1903, 616—617). I have worked out a table giving the values of the colour depths in a one inch (really $\frac{13}{14}$ inch) Lovibond cell from 0.1 unit to 6.2 units of yellow, representing a range of 0.002 to 0.139% of nitric nitrogen in the diluted yellow solution (Table C).

TABLE C.

Estimation of nitrogen as nitrates by phenoldisulphonic acid. Value of yellow units (Lovibond) in a $\frac{1}{16}$ -inch cell.

Yellow units.	Mgrms. N in 100 c.c.	Yellow units.	Mgrms. N in 100 c.c.	Yellow units.	Mgrms. N in 100 c.c.
0.1	0.002	2.2	0.050	4.3	0.095
0.2	0.004	2.3	0.053	4.4	0.098
0.3	0.005	2.4	0.055	4.5	0.100
0.4	0.007	2.5	0.057	4.6	0.103

0.6	0.011	2.7	0.062	4.8	0.108
0.7	0.014	2.8	0.064	4.9	0.109
0.8	0.015	2.9	0.066	5.0	0.111
0.9	0.017	3.0	0.069	5.1	0.113
1.0	0.020	3.1	0.070	5.2	0.115
1.1	0.023	3.2	0.072	5.3	0.118
1.2	0.025	3.3	0.074	5.4	0.120
1.3	0.027	3.4	0.077	5.5	0.122
1.4	0.030	3.5	0.080	5.6	0.123
1.5	0.032	3.6	0.082	5.7	0.125
1.6	0.034	3.7	0.0832	5.8	0.128
1.7	0.037	3.8	0.086	5.9	0.130
1.8	0.039	3.9	0.087	6.0	0.132
1.9	0.042	4.0	0.090	6.1	0.135
2.0	0.045	4.1	0.092	6.2	0.139
2.1	0.048	4.2	0.093		

An actual example of working may be of value. Known amounts of the three acids were used in such dilution as fairly to represent a canal or river water containing effluents from picric acid works.

(1) 70 c.c. of the solution when tinged with methyl red required 6.9 c.c. of $N/10$ sodium hydroxide for neutralisation.

(2) 10 c.c. of the solution after mixing with 5 c.c. of $N/10$ sodium hydroxide was evaporated to dryness on the water-bath. The residue was well mixed with 1 c.c. of phenoldisulphonic acid mixture, and after warming gently for about 5 minutes the acid liquid was diluted with about 50 c.c. of water, transferred to a 100 c.c. flask, made alkaline with ammonia, cooled to 15°C.,

and diluted to 100 c.c. In the $\frac{3}{16}$ inch glass cell the colour depth was found to be exactly 2.3 yellow units (Table C).

(3) The original solution of the three acids gave a colour in the $\frac{3}{16}$ inch glass cell equal to 0.8 yellow unit. Reference to the table shows that this is equivalent to 0.28 grain of picric acid per gallon.

The calculation is now simple: 70 c.c. contains 0.28 mgrm. of picric acid, equivalent to 0.0121 c.c. of $N/10$ NaOH. The nitric nitrogen found was equal to 0.0533 mgrm. in 100 c.c. or 0.0371 mgrm. in 70 c.c., equal to 0.167 mgrm. of nitric acid, representing 10 times (on account of the tenfold dilution) the amount, or 1.67 mgrms. of nitric acid in 70 c.c. of the original liquid.

1.67 mgrm. of nitric acid is equal to 0.2650 c.c. of $N/10$ NaOH. 0.28 mgrm. of picric acid is equal to 0.0121 c.c. of $N/10$ NaOH.

Therefore the combined nitric and picric acids represent in 70 c.c. 0.2771 c.c. of $N/10$ NaOH.

The total acidity of 70 c.c. equalled 6.9 c.c. of $N/10$ sodium hydroxide, hence the acidity due to sulphuric acid is 6.6229 c.c., or 32.48 grains of H_2SO_4 per gallon.

Grains per gallon.	Present.	Found.	Error.
Sulphuric acid	32.60	32.48	— 0.12
Nitric acid	1.76	1.67	— 0.09
Picric acid	0.28	0.28	nil.

I give the following example to show the necessity of deducting the requisite number of yellow units from the cell reading obtained in the estimation of the nitric acid.

4.4 units were required to match the yellow colour. 0.7 unit was found to match the yellow colour of the liquid itself when a similar tenfold dilution was made.

3.7 yellow units were therefore required for the colour developed by the nitric nitrogen alone.

Grains per gallon.	Present.	Found.	Error.
Sulphuric acid	15.0	14.2	— 0.8
Nitric acid	2.5	2.63	+ 0.13
Picric acid	2.5	2.52	+ 0.02

Only 70 c.c. of the liquid was used for the total acidity and an error of only 0.16 c.c. of the $N/10$ alkali was required to account for the error of — 0.8 grain of sulphuric acid per gallon.

The intensity of the colour given by picric acid to water is evident from the fact that when pure water contains as little as the $\frac{1}{325}$ th grain per pint of picric acid it will require 2 units of yellow to match the colour in a $\frac{1}{16}$ -inch Lovibond's cell. This represents about $\frac{1}{32}$ grain of picric acid per gallon.

My attention was naturally directed to other methods of estimating nitric nitrogen in the mixtures. Unfortunately the Halle zinc-iron and caustic soda method results in the decomposition of some 37% of the picric acid, and cannot be used. Moreover, any nitric nitrogen reduction process, zinc copper couple for example, applied to extremely small amounts of substance requires final Nesslerisation of the small amount of ammonia, and no advantage over the phenoldisulphonic acid method can reasonably be expected.

"Nitron" is now unobtainable, moreover it was quoted at about 10s. an ounce before the war. As a 10% solution of the acetate is used in liberal amounts the process is costly. Also nitron pre-

precipitation is only applicable to appreciable weights of nitric acid and nitrates. As the total amount of nitric acid in the samples frequently supplied to analysts does not exceed a few centigrams, a gravimetric process is scarcely advisable.

The action of dilute solutions of sulphuric, nitric, and picric acids upon iron.

Waters containing picric acid effluents often come in contact with iron machinery and iron boilers. It has been suggested that even small amounts of nitric acid in the presence of larger proportions of sulphuric acid might produce corrosive effects far greater than the mere acidity might indicate.

Very dilute solutions of sulphuric acid as compared with solutions containing the same molecular equivalents of nitric acid act even more readily upon chemically clean wrought iron surfaces. Strips of wrought iron 3 in. by 1 in. were immersed for three days at 10°–20° C. in 500 c.c. of acid solutions. The following figures show the proportions of iron dissolved:—

Acid.	Iron dissolved.
N/250 sulphuric acid	82
N/250 nitric acid	49
Equal parts of N/250 sulphuric and nitric acids	53

With solutions of ten times these acid strengths the amounts dissolved were 529, 512, and 500 respectively, or in the ratios 105·8 : 102·4 : 100·0.

The dilute nitric acid forms a brown-red coating upon the iron sheet and this, in the case of very dilute solutions, may well prove slightly protective.

When the diluted acids alone and mixed are boiled down upon sheet iron, a copious brown-red coating appears only in the case of the solutions containing nitric acid.

Addition of water with re-evaporation caused a much greater action upon the iron in the case of the nitric acid solutions. The percentages of action in this case were sulphuric acid, 100; nitric acid, 127; mixed acids, 116.

It was evident that hydrolytic action was caused by the evaporation process in the case of the nitrate of iron:

$\text{Fe}_2(\text{NO}_3)_6 + 6\text{H}_2\text{O} = \text{Fe}_2(\text{OH})_6 + 6\text{HNO}_3$.

The nitric acid set free again acts upon the iron. Nitric acid solutions when concentrated in boilers will therefore produce extensive corrosive action.

Picric acid of N/250 strength (0·0916% equal to 64·12 grains per gallon) readily acts upon iron. My experiments show that as compared with sulphuric acid the amounts of iron dissolved are roughly proportional to the molecular equivalents, 49 parts of sulphuric acid producing the same result as 229 parts of picric acid.

DISCUSSION.

The CHAIRMAN said that for measuring the action of the effluents upon iron more details of the method used were desirable. The action was made more complicated and comparison more difficult by factors not noticed at first sight, which provided a wide sphere for discussion. He was not surprised that tintometry gave the best results in estimating very small quantities of picric acid but asked whether the process was possible in artificial light, and if so what precautions were necessary?

Mr. LOWSON suggested that the method used for the determination of nitric acid would include also any nitrates present, and that if the latter were in appreciable amount, errors would be introduced.

Mr. F. HULSE said that he had obtained constant

results by making alkaline with caustic soda, evaporating down, and testing in the nitrometer. He quite agreed with Mr. Richardson with regard to the benzol extraction process.

Mr. F. W. BRANSON said that in his experience the best artificial light was supplied by the new electric lamp known as the "Pointolite."

Mr. W. McD. MACKEY said that he had used the colorimetric process and found that by making the solution alkaline with caustic soda the colour was deepened. With regard to the action of acids upon iron it had been found that steel was more readily attacked than wrought iron.

Mr. MILLER agreed with Mr. Mackey with regard to the deepening of the colour by making alkaline with caustic soda. Tatlock had found (see this J., 1904, 429) that in the presence of chlorides the phenolsulphonic acid method gave low results for nitrates. In his experience methyl red gave a very sharp end point.

The CHAIRMAN shared the high opinion of methyl red as an indicator, but said that the use of any indicator involved certain assumptions which Professor James Walker had shown how to avoid in studying the action of liquids on metals.

Mr. H. J. HODSMAN asked if Mr. Richardson had observed that the presence of picric acid accentuated the corrosive action of acid effluents. If corrosion were electrolytic in character, it might be facilitated by the depolarising action of a compound so highly nitrated as picric acid. In support he mentioned the rapid oxidation of hydrogen by sodium picrate in presence of colloidal palladium—a reaction which had been used in gas analysis for the estimation of hydrogen.

Mr. B. A. BURRELL mentioned that during the past summer he had inspected some agricultural property the vegetation on which had been badly damaged by the fumes arising from a recently erected picric acid works.

The CHAIRMAN said that some experiments with regard to the action of acids on lead had been carried out some years ago by Lunge and a collaborator.

Mr. BEDFORD asked if the West Riding Rivers Board was taking any action with regard to the pollution of streams with these effluents.

Mr. RICHARDSON replied that with regard to the action of acids on iron, sulphuric acid gave a clean surface while nitric acid gave a rusty appearance, and for a time the coating of oxide was slightly protective. Daylight was decidedly the best light to use but fairly accurate results had been obtained with the "Dufton Gardner Lamp." If the effluent were treated with soda ash it did not cause any undesirable action on boilers. When nitrates were present the sulphuric acid liberated the nitric acid; the nitrogen might therefore be regarded as being present as free nitric acid. No appreciable amount of nitrates need be expected in either the picric effluents or in river and canal water. With the nitrometer accurate results might be obtained with large quantities, but for small quantities it was useless. He had found that caustic soda did not deepen the colour. In his experience, also, the presence of large quantities of chlorides interfered with the results; in such a case the chlorides must be removed, but in ordinary river and canal waters one did not find an excess of chloride.

He had not made any experiments with regard to the combined action of picric, sulphuric, and nitric acids on lead.

The use of lime for neutralising the effluents was objectionable because it made the water unfit for boiler purposes. He had reason to believe that the authorities were fully alive as to pollution by picric effluent.

Communication.

A PRELIMINARY INVESTIGATION ON THE ESTIMATION OF FREE AND COMBINED SULPHUR IN VULCANISED RUBBER, AND THE RATE OF COMBINATION OF SULPHUR WITH DIFFERENT TYPES OF PLANTATION PARA RUBBER.

BY B. J. EATON AND E. W. F. DAY.

The many methods of estimation of sulphur by oxidation which involve the use of nitric acid, bromine, and alkaline fusion were tried and found unsatisfactory (*cf.* a paper by H. E. Potts in "The Rubber Industry," 1911).

Rheinhardt's proposed method of burning the rubber in a current of oxygen and absorbing the resultant gases in brominated hydrochloric acid, fails to arrest *all* the sulphur compounds liberated. Gaunt (*Analyst*, 1915, 40, 9; *this Journal*, 1915, 146) suggests hydrogen peroxide as the absorbent and uses a short glass tube in place of the usual combustion "boat." He then titrates the sulphuric acid produced or weighs as barium sulphate.

Our experiments showed that the acidity could only be relied on when the combustion was complete. In practice, perfect combustion is difficult of attainment and this modification was abandoned. It was even found that, without the use of platinumised asbestos, hydrogen peroxide allowed some escape of compounds containing sulphur, as also did strong solutions of barium peroxide in hydrochloric acid. Strong caustic soda, however, stopped *all* sulphur compounds without the use of platinumised asbestos in the combustion tube, and on subsequent acidification with brominated hydrochloric acid the whole of the sulphur was recovered as barium sulphate. The type of combustion, *i.e.*, whether "complete" or slightly smoky, has little effect on the results. Full working details of the new method are as follows:—

The vulcanised rubbers are crumbed between small crepeing rollers and representative portions are selected for analysis. These in turn are carefully picked over under a lens for "skin," insufficiently crumbed particles, etc., and are finely snipped with scissors. 0.1374 gm. of each sample is wrapped up in little filter paper packets marked in pencil for identification later. These are stacked together in bundles of six or eight and extracted in a Clayton Beadle and Stevens' Soxhlet apparatus (*Analyst*, April, 1913) with boiling acetone. The extraction is carried on for about 100 hours and at suitable intervals the packets are opened, teased out with a finely pointed glass rod and forceps, and repacked. They are stacked again into bundles and subjected to further extraction. In the present work each sample was teased out in this way three times. On completing the extraction, the determination of sulphur should be carried out as soon as possible. It is found in practice that a more easily controlled combustion is obtained with the freshly extracted rubber than in the case of extracted samples that have been preserved for, say, a month. Furthermore, such samples ignite more easily and so dry distillation before ignition is reduced to a minimum.

The paper packet is pushed into a glass tube 3 cm. long \times 1 cm. diameter, sealed at one end, and the whole placed in the combustion tube with

the open end forward, and about 8 cm. from the forward end. The combustion tube is of hard glass and about 20 cm. long and 2 cm. in diameter. At the forward end it is drawn out and bent downwards to take a short piece of rubber tubing which connects it to the absorption apparatus.

This latter consists of two 15 cm. \times 1.5 cm. test tubes, the first containing 1.5 c.c. and the second 0.2 c.c. of 7N aqueous sodium hydroxide. This strength is used as being the strongest that one can employ without fear of the leading tube jets being blocked by the carbonate formed during absorption.

As a safeguard against the necessity of having to rush through a quick current of oxygen, if the combustion becomes a little violent, it is advisable to attach a couple of small U-tubes filled with glass beads and moistened with a little 2N caustic soda to the absorption tubes.

Our practice here, as already pointed out, is to extract the samples in groups of six or eight, and to control the results by estimating the soluble sulphur dissolved out of the group by the acetone. It is convenient, therefore, for us to deal with the sulphur compounds absorbed by the U-tubes after the combustion of all the members of each group. Thus the barium sulphate so obtained is determined separately for each group. A group of six or eight members usually returns 0.5 to 2 mgrms. which is distributed evenly among the members of the group (see Table IV. under group correction).

To effect the combustion, which occupies ten to fifteen minutes, dry oxygen is passed slowly through the apparatus and a strong roaring flame is applied about 2 cm. in front of the mouth of the small tube. This is maintained until the paper packet begins to darken. To minimise the chance of a minor explosion spoiling the estimation, a strong current is now passed along the tube (up to 400 c.c. per minute) until ignition occurs. The current is then much reduced, and regulated so as to secure a small bright flame with as little smoke as possible.

When nothing but a whitish ash remains in the smaller tube, the test tubes and leading tubes are washed into a 200 c.c. beaker to which later are added the washings of the combustion apparatus obtained as follows:—The large combustion tube is rinsed out with very dilute brominated hydrochloric acid and the small combustion tube is boiled in this mixture until all bromine is driven off. The liquid is then cooled and washed into the 200 c.c. beaker. The total bulk is now made up to 100 c.c. or over and 6 c.c. of brominated hydrochloric acid (pure acid 10 parts, water 10 parts, and bromine 1 part) added from a burette. The liquids are gently mixed with a glass rod, covered with a watch glass, and allowed to stand. After evaporating off the excess of bromine, filtering, and making up to 50 c.c., the sulphate in solution is precipitated by adding 2 c.c. of a 10% barium chloride solution. The filter paper and precipitates are burnt together in a muffle; there is no risk of reducing the sulphate to sulphide. All the filtrates from the first fifty-nine estimations in Table IV. were collected and mixed, and the recovered barium sulphate appears as a percentage of sulphur distributed among the samples in Table IV., column 6.

Each 0.01 gm. of barium sulphate represents 1% of sulphur in the rubber. The following figures (Table I) illustrate the constancy and accuracy of this combustion method.

An unvulcanised mixing (Slab rubber No. 221 S. 3, A), containing 90% of rubber and 10% of sulphur, was analysed, the samples being taken from different parts of the mixing.

TABLE I.

No.	Total sulphur on the mixing.
	%
1	9.81
2	9.82
3	9.76
4	9.85
5	9.79
6	9.81
Mean	9.81

After vulcanising this mixing for 3 hours, which yielded a much overcured rubber, containing consequently a high percentage of combined sulphur, the same mixing yielded the results given in Table II.

TABLE II.

No.	Total sulphur on the mixing.
	%
1	9.80
2	9.93
3	9.89
4	9.91
5	9.98
6	9.81

Combined sulphur (sulphur of vulcanisation).

On extracting with acetone, the "free" sulphur is removed and the residue contains the "combined" sulphur.

As illustrating the constancy and accuracy of the acetone extraction process employed, followed by the combustion of the residual rubber as already described, the following duplicate figures serve. The results in Table III. below were obtained on the same sample (No. 221 S. 3, A) vulcanised for different periods.

Determination of sulphur in vulcanised rubber prepared from different types of plantation Para rubber.

In order to trace the combination of sulphur with samples of plantation Para rubber having different rates of cure, as indicated by the physical properties of the vulcanised material, a complete set of results arranged in three tables (IV., V., and VI.) was obtained in the case of samples No. 244 A, B, and C, consisting of specimens of slab (244 A), sheet (244 B), and crepe (244 C). All of these samples were prepared from similar latex and under identical conditions except as to machining.

TABLE III.

Number of hours vulcanised.	Combined sulphur per cent. on the mixing.	Type of combustion.	Combined sulphur per cent. on the mixing.	Type of combustion.
	(Original.)		(Duplicate.)	
0	0.10	—	0.15	—
$\frac{1}{2}$	1.73	Clean.	1.82	Clean.
$\frac{1}{2}$	2.44	Slow, smoky.	2.51	Combustion rapid at start.
$\frac{1}{2}$	3.06	Slow start; normal otherwise	2.93	Clean start, later very rapid.
1	4.18	Unexpected start; rapid; much smoke.	3.96	Clean, quick combustion.
$1\frac{1}{2}$	4.38	Very badly smoked.	4.38	Clean, trifle dry distilled at start.
2	6.42	Rapid start, normal later.	6.38	Rapid start; very slow later.

(NOTE.—The optimum cure of this sample was taken to be 1 hour 8 min., which corresponds to 4.22% combined sulphur.)

TABLE V.

Results of estimation of the "soluble sulphur" extracted from the various groups; and the balance between this sulphur and the residual sulphurs of Table IV.

Group No.	Grammes of BaSO ₄ (less blanks).		Total BaSO ₄ grammes.	Total sulphur in group %
	Soluble.	Combined.		
1	0.4241	0.2602	0.6843	9.78

Method of estimation of soluble sulphur.

The acetone extract of each group was dried, treated under a reflux condenser with nitric acid and bromine mixture, evaporated to dryness with a little potassium nitrate, mixed with potassium chlorate (1 part) and fusion mixture (6 parts), ignited in a nickel dish, the aqueous extract filtered, acidified with hydrochloric acid, boiled to remove carbon dioxide, diluted to half a litre, and precipitated with 10 c.c. of 10% barium chloride.

Table V. shows the amount of "soluble sulphur" weighed as barium sulphate obtained from each group. As will be seen, the estimation of the soluble sulphur in this manner acts as a check on the operations, and the figures in the last column show that practically all the sulphur is accounted for.

In Table VI. the results are rearranged for each of the specimens 244 A, B, and C, in order to show the combination of sulphur with progressive periods of heating.

It will be seen from Table VI. and Diagram I. that the figures give smooth curves up to seven hours for the slab (244 A), and ten hours for the sheet (244 B) and crepe (244 C).

Physical properties of the vulcanised rubbers.

In order to compare the rate of combination of the sulphur in the case of each type of rubber, with

the tensile properties of the vulcanised material, we include the following diagram (Diagram II.) of the load-stretch curves for the different periods of cure at 1 hour intervals, in which the progressive state of cure of the samples as judged by their tensile properties can be seen at a glance. The curve marked X in each case is the curve of optimum time of cure as estimated by our standard curve method (*vide* this Journal, 1916, 35, 715—728. "Vulcanisation experiments on plantation Para rubber. II. The cause of variability and some contributory factors," by B. J. Eaton and J. Grantham) but, as we have stated elsewhere, the standard curve obtained at this "optimum cure" may not be strictly correct, although it constitutes a good basis of comparison between different rubbers, since it is relative rather than absolute. It represents, however, a similar state of cure in each sample.

Young (*loc. cit.*) and other experimenters have found.

The small deficiencies from 10% are attributed to small losses during the mechanical processes in mixing, which up to the present have not been traced, to slight increases in weight such as are sometimes observed after mixing, and to the addition of French chalk to the surface of the mixings. It is possible also that some sulphur remains combined in the insoluble ash obtained on combustion. Some slight loss is unavoidable also in the process of teasing out the residues during the acetone extraction.

We are thus able to balance the free sulphur and the combined sulphur against the total sulphur and against the original sulphur put into the mixing, as is shown in Table V. (Note:—The combustion method here described, would, of course, be inadmissible for estimating sulphur in vulcanised mineral mixings.)

Industrial Notes.

NATIONAL SULPHURIC ACID ASSOCIATION.

IS a circular letter addressed to about fifty of the principal sulphuric acid manufacturers in this country by the managing director of a firm of acid makers, the writer says that for a long time he has been anxious that the makers should meet together with the object of finding ways and means to prevent the absolute chaos which must inevitably arise in the sulphuric-acid trade upon the conclusion of peace if manufacturers are not more closely associated.

Continuing, the writer says:—

"Before the war is over—and in the opinion of many this desirable end is still far distant—the daily tonnage of sulphuric acid consumed in the manufacture of explosives in this country will have attained a stupendous figure. The further we are from the cessation of hostilities, the greater will be the paralysis in the sulphuric-acid trade when that time does arrive, so that it behoves us to make every provision with the best possible equipment in our power to enable us to face the situation which will then obtain.

"At that time no maker will know at what price to sell his product, owing to the impossibility of accurately forecasting the cost of production.

"The advantages of co-operation at such a critical time are self-evident, and this one reason alone convinces me of the desirability of the makers extending forthwith a serious effort to consider means of overcoming the difficulties which have been the cause of lack of co-operation in the past. The idea I have in mind is that every maker shall exercise his strongest endeavours towards the formation, in his district, of an association, of which he would be a member, similar to that now existing in the Midland district, in which all interested in the sulphuric-acid trade, dealers as well as makers, are pledged to co-operation.

"In South Wales, also, there has been in existence for very many years past an excellent association, but there are one or two important makers in that district who are not members, and these abstentions from membership must of necessity greatly impair the usefulness of any association.

"Surely every local association should represent every local maker, and the appointed representatives of all the local associations throughout the country should constitute a national association. It should be the function of these local associations to prevent fruitless competition.

"I desire that the sulphuric-acid trade shall be closely united for the reason that in the future any trade without co-operation is bound to be at a great disadvantage to a similar trade closely associated in other countries.

"It seems to me that if at the termination of the war the whole sulphuric-acid trade were so united as to be in a position to speak with a single voice, then a trade of such vital national importance as sulphuric acid should be able to influence legislation necessary to its interests and the national welfare.

"Legislation could materially assist our trade with specially low freights upon the imported sulphur material, reduce railway rates in this country for carrying the necessary raw material and finished product, and, if need be, grant bounties for the treatment of special classes of sulphur material.

"Again, surely it is not in the national any more than in the individual interest for manufacturers in the same trade to be bidding against each other for pyrites and other sulphur material imported from foreign countries, such as Norway and Spain? Would it not be preferable if the trade made its purchases through one organisation, thereby eliminating competitive bidding and obtaining the advantage which is always obtained by a large over a small buyer?

"As mutual confidence became engendered through co-operation, such further economies would gradually follow as were in the national interest. For example, costs of production would be reduced all round by inter-comparison derived from more economic administration, distribution, and manufacture, thereby benefiting the consumer by reducing the selling price without impairing the profit-earning capacity of the vast capital invested in the sulphuric-acid trade.

"Where industries are so organised I can conceive even a British Government consenting to legislation whereby the entirely wasteful introduction of capital by superfluous and speculative parties without experience in the trade would be prohibited until the merits of the proposition had been examined by a committee of expert manufacturers in conjunction with expert Government representatives.

"In my opinion, this country will be placed for many years after peace is declared at such a disadvantage as compared to neutrals, such as America, through the loss of lives and treasure in the war, that I believe it will be found in the national interest to prevent men inexperienced in any trade from exploiting their own or public money in competition with existing interests. It must either mean a waste of that capital or reduction in the capital value of existing interests. In either case this seems to be a waste of the nation's resources. It is the duty of the nation's future leaders to do all in their power to prevent the individual even as much as the public from rashly investing his capital.

"Surely hereafter it is for the Government to take such control of the community's wealth as will prevent it being invested without a reasonable prospect of good interest."

The letter concludes with a request for information in regard to the existence of local sulphuric acid associations in the various districts, asking if manufacturers will take steps to create local associations in districts where such do not exist at present.

ASSOCIATION OF BRITISH CHEMICAL MANUFACTURERS.

THIS Association was registered on December 28th as a company limited by guarantee, and not having a capital divided into shares, with an unlimited

number of members, each liable for not more than £25 in the event of winding up, to promote co-operation between British subjects engaged as manufacturers in the chemical or closely allied industries; to place before Government and Government officials and others, either in the British Dominions or elsewhere, the views of members of the Association and others upon matters affecting the chemical industries; to develop technical organisation; to promote industrial research, industrial efficiency and the advancement of applied industry, etc. (see this Journal, 1916, 561, 1040).

The management is vested in a Council, consisting of not less than 16 or more than 20, the first members of which are:—

Dr. E. F. Armstrong (Joseph Crosfield and Sons, Warrington).

F. H. Carr (Boots Pure Drug Co., Ltd., Nottingham).

Dr. C. Carpenter (South Metropolitan Gas Co., London).

Dr. M. O. Foster, F.R.S. (British Dyes, Ltd., Huddersfield).

J. Gray (Lever Bros., Ltd., Port Sunlight).

C. A. Hill (British Drug Houses, Ltd., London).

N. N. Holden (Hardman and Holden, Ltd., Manchester).

D. L. Howard (Howards and Sons, Ltd., Ilford).

C. P. Merriam (British Xylonite Co., Ltd., Hale End).

The Right Hon. Sir Alfred M. Mond, Bt., P.C., M.P. (Almond Nickel Co., Ltd., London).

Max Muspratt (United Alkali Co., Ltd., Liverpool).

R. G. Perry (Chance and Hunt, Ltd., Oldbury).

Sir William Pearce, M.P. (Spencer Chapman and Messel, Ltd., London).

R. D. Pullar (J. Pullar and Sons, Ltd., Perth).

A. T. Smith (Castner-Kellner Alkali Co., Ltd., Liverpool).

The Right Hon. J. W. Wilson (Albright and Wilson, Ltd., Oldbury).

Dr. A. Ree (President Society of Dyers and Colourists).

There are to be "Group" Committees, each consisting of not less than three members, representing: Group 1. Acids (including acetic and oxalic), carbonic acid, hydrogen, oxygen and gases, alum, chrome, zinc, copper, and iron compounds, fertilisers (including superphosphates). Group 2. Alkalis, cyanides, chlorine and compounds, silicates, chlorates, borax, hydrogen peroxide, magnesia compounds (not medicinal). Group 3. Fats, greases, waxes, resins, glycerin, soap. Group 4. Gelatin, sizes, glue, varnishes, paints, polishes, tanning. Group 5. Distillation of coal, shale, oils, and wood, alcohol, acetone, coal-tar primary products (including ammonia and ammonia products), charcoal, fuel. Group 6. Fine chemicals, analytical, pharmaceutical, photographic, rare earths, synthetic essences, and perfumes, alcohol derivatives, ethers. Group 7. Phosphates, manganese, potassium, sodium, barium, calcium, cadmium, etc., lead, arsenic, antimony, tungsten, molybdenum, etc. Group 8. Cellulose products (including paper), celluloid, rubber and substitutes. Group 9. Explosives, and dyes and their intermediaries. Group 10. Glass, porcelain, pottery, refractory materials, lime, cement, chemical-resisting materials. Group 11 (allied industries). Bleachers, dyers, and textile printers.

TRADE DURING AND AFTER THE WAR.

In the Third Report of the Special Committee of the London Chamber of Commerce on "Trade During and After the War," as adopted at a special meeting of the Council on December 20th, the Committee affirm their conviction that the

practical application of measures for the extension of trade and industry after the war will be mainly a matter for private enterprise, for individual and collective efforts, voluntarily undertaken, supplemented and not superseded by Government action.

Among the State-aided efforts recommended are:

The early adoption of a tentative and *ad valorem* tariff.

A Ministry of Commerce and Industry, for the promotion of business interests.

The improvement of the commercial side of the Consular Service.

Restriction of the operations of enemy traders within the Empire.

State aid in improving the means of transport on land and water, and penalising enemy shipping.

The co-operation of the State in the promotion of trade banks to furnish financial accommodation of a special kind to traders doing business abroad.

Employers and employed.

The Committee deal at length with the question of future relations between employers and employed, and make the following recommendations as a basis for negotiation between capital and labour.

(a) As regards the remuneration of employees the principle of payment by results should as far as possible be adopted by employers and employed.

(b) The basis of rates of payment for labour should involve such a scale as will ensure for all willing and efficient workers a fair and reasonable standard of living.

(c) The Government should afford opportunities for considering the amendment of the Trade Disputes Acts and of any provisions of the Factory and Workshops Acts other than those relating to the health of the workers.

(d) Encouragement should be given, as far as possible, to profit-sharing and co-partnership agreements, or premium and bonus systems on lines which have proved beneficial to employers and employed in the past, subject to the special conditions of particular trades, and to the maintenance of the standard of wages.

Industry after the war.

The Committee also make the following suggestions with regard to the development of industry after the war:

The utilisation, for the purposes of private enterprise after the war, of factories now engaged in the production of munitions, in connection with industries for which they may be suitable.

The encouragement of the technical education of younger employees by giving them greater facilities for attending the necessary classes beyond the statutory school age.

The amendment of the Patents, Designs and Trade Marks Acts so far as they may be restrictive of the adoption of new processes, labour-saving appliances, and new inventions.

The improvement and cheapening of means of transport by rail, road, and waterways including canals.

Increased facilities for obtaining information through Government Departments regarding competition in the markets of the world and new openings for the sale of British goods.

Such further direct representation of manufacturers individually and collectively in the Dominions, Allied, and neutral countries as may be in harmony with the legitimate interests of the merchant.

A more sympathetic attitude on the part of the Government in regard to the promotion and amendment of legislative measures affecting British industry, especially in relation to conditions of labour.

A preference on the part of Government Departments and Local Authorities for goods produced within the British Empire when needed for the requirements of the State.

Other sections of the Report deal with commercial and industrial policy, the treatment of enemy shipping, and finance and insurance.

GOVERNMENT LABORATORY : REPORT OF THE GOVERNMENT CHEMIST ON THE WORK OF THE — FOR THE YEAR ENDED 31st MARCH, 1916. (Cd. 8391.)

THE number of samples examined during the year was 239,706, as compared with 230,101 during the previous year, exclusive of those dealt with at the chemical stations; 8901 samples of food were examined in connection with the supply of the Expeditionary Forces.

Beer, brewing materials, cider, and perry. 350 samples of finished beer were examined for saccharin, saponin, and other prohibited ingredients, but except occasional traces of arsenic, nothing of a deleterious or illegal character was observed. 11,198 samples of unfinished worts and beers were examined. The original gravity had been under-declared in 2931 cases, the percentage of under-declarations having been 33.3%, compared with 12.6% in 1911-15. Twelve samples imported as "malt extract" were found to correspond with beer and were charged duty accordingly. Of 1797 samples of beer and brewing materials examined for arsenic, only six were found to contain arsenic in excess of the Royal Commission limits. The highest proportion of arsenic found in beer or wort was 1/26 grain per gallon. Three samples, out of 123 of imported cider examined, were found to be factitious and assessed for duty on their spirit content. One sample of commercial cider was found to contain 1.6% proof spirit, and six samples purchased as cider were prepared liquors containing no apple juice.

Spirits. Eighteen samples of fusel oil from distilleries in this country were examined, and one was found to contain more than 15% of proof spirit. Of ten samples of imported fusel oil, none contained more than this limit. Evidence of the extraction of spirit from the wood of spirit casks ("grogging") was obtained in several cases, and proof that spirit had been obtained by illicit distillation was furnished in three cases. No evidence of the illicit use of methylated spirit was obtained in the 3081 liniments, hair washes, etc., tested, but in a number of cases the declared spirit strength of spirituous preparations for export was over-stated. In 59 cases importations entered as "wood naphtha" or "crude methyl alcohol" were found to consist of methyl alcohol so purified as to be liable to spirit duty. For use in preparing methylated spirit, 1353 samples of wood naphtha and of mineral naphtha were approved, and 21 samples of petroleum ether, used in admixture with methylated spirit in the manufacture of felt hats, were also approved. A considerable increase in the use of all these denaturants is noted. For the purpose of controlling the use of methylated spirit in connection with manufacturing operations, 268 samples of still residues, articles manufactured with industrial spirit, and preparations containing such spirit were examined, and in connection with the use of duty-free alcohol 28 samples of spirit and 83 samples of specially denatured alcohol and denaturing substances were submitted and approved.

Sugar and saccharin. 21,682 samples of sugar and articles containing sugar were examined for

assessment of duty or drawback: of these 21 samples consisted of sugar, molasses, and beetroot from the Cantley beetroot sugar factory. Of 68 samples of honey examined, five afforded evidence of the addition of invert sugar. In 38 samples out of 309 examined, saccharin was found to be present.

Matches. No evidence of the presence of white phosphorus was discovered in the 375 samples of matches examined.

Imported dairy products. Of the 82 samples of condensed milk examined, 56 were condensed whole milk (8.1 to 11.3% fat) and 26 condensed skimmed milk. In several samples the concentration was low, the milk having been evaporated to only half its bulk. All the samples were free from preservatives. Three samples of skimmed milk powder were taken from packages not bearing the description "skimmed milk," and in three other cases the labelling of the packages was unsatisfactory. The greatest amount of boric acid found in the samples of "churn cream" examined was 0.45%. Of 1037 samples of imported butter, 402 contained boron preservative and 42 added colouring matter. Six samples of imported butter contained more than 16% of water. There was no evidence of the presence of fat other than butter fat in any of the samples. In 42 cases the Reichert-Wollny number fell below 24. Of 524 samples of imported margarine, none contained more butter fat than is legally permissible, but excess of water was found in eight cases. No foreign fat was detected in the samples of imported cheese, but in some cases the percentage of fat was low. Forty-five samples of butter out of 307 samples taken under the Butter and Margarine Act, contained excess of water and five samples were mixtures of butter and margarine.

Sheep dips. Thirty-one samples were examined in connection with applications from manufacturers to include their preparations in the official "Schedule of efficient dips." Twelve samples were deficient in active ingredients at the proposed dilution, and in ten cases the formulae submitted required modification. Twelve samples of approved dips were purchased, and in three cases it was found that they had not been prepared according to the formulae previously submitted and approved.

River pollution. Two sea trout taken from a stream believed to have been polluted, contained small quantities of copper, lead, and zinc.

Glazes. The samples examined were generally found to comply with the Home Office requirements. Samples of lead glaze were examined as regards total lead content and amount of lead soluble in dilute hydrochloric acid. In 19 cases where lead poisoning had occurred, almost all the lead was soluble in the dilute acid.

Sale of Food and Drugs Acts. Seventy-five samples were referred by magistrates under these Acts, viz., milk 61, butter 5, rum 2, cream, whiskey, coffee, and ipecacuanha wine, one each. In ten cases the result of the examination of the Government Laboratory differed from that of the public analyst.

Fertilisers and Feeding Stuffs Act. Nine fertilisers and 35 feeding stuffs were examined. The fertilisers consisted of superphosphate, basic slag, bone meal, and potato manures. They were deficient in phosphates or nitrogen. Several of the samples of feeding stuffs were deficient in oil or albuminoids, and in some cases a considerable proportion of unsuitable substances was present.

Reference is also made to work carried out by the Laboratory for the Admiralty, Central Control Board, Crown Agents for the Colonies, Geological Survey, India Office, Inland Revenue, Local Government Board, Post Office, Stationery Office, Trinity House, Board of Trade, War Department, War Trade Department, Office of Woods and Forests, and Office of Works.

UTILISATION OF TERRESTRIAL HEAT.

AN interesting description is given by Professor Luiggi, in a recent issue of *Engineering*, of the attempts made to utilise terrestrial heat in Italy. It is well known that in Central Tuscany, near Volterra, there are numerous cracks in the ground, from which powerful jets of hot steam ("Soffioni") are projected into the air, carrying with them boric acid and other substances; for many years these have been utilised as a source of boric acid and borax, but the greater part of the steam has been wasted, with the exception of a small quantity occasionally used for warming houses in an adjacent village.

The first attempt to utilise this superheated steam as a source of power was made in 1903 by Prince Ginori-Conti, who applied it to a small rotary motor, then to a reciprocating steam engine connected with a dynamo, which generated sufficient current to light part of the borax works. A more ample supply of steam was obtained by boring holes in the ground, lined with iron pipes, to a depth of 300 to 500 ft. These holes vary from 12 to 20 in. in diameter and from them the steam issues at a pressure of 2 to 3 and occasionally 5 atmospheres and at a temperature of 150°–190° C. For several years the flow of steam from these jets has not abated, nor do new borings appear to affect preceding ones providing the distance apart is not less than 50 ft. Experiments showed that each bore-hole could produce steam at the rate of 15,000 to 25,000 kilos. per hour, at 150° C., i.e., about 1000 to 2000 theoretical horsepower per hour.

In 1906 the steam was applied to an ordinary steam engine of about 40 H.P., with satisfactory results as far as power is concerned, but the

impurities in the steam seriously corroded the iron structure. To avoid this difficulty the steam was applied instead of fuel to a multitubular boiler, in which steam was produced at 2 atmos. pressure, then passed through a superheater, and afterwards used for driving a 300 H.P. condensing steam engine, directly connected with a triphase electric generator, which supplies the works and villages round Larderello. This installation had been working successfully for several months before war broke out.

The enormous increase in the price of coal has resulted in further plant being installed, three groups of condensing turbo-electric engines, each of 3000 kw., having been put down. The engines work with steam at 1½ atmos., generated in multitubular boilers arranged vertically and with aluminium tubes. The temperature of the steam falls from 180° to about 120° C. in the boilers, and it is then used for the borax works.

The current, generated at 4500 volts and 50 periods per second, is converted in an oil transformer to 36,000 volts and sent to Florence, Leghorn, Volterra, Grosseto, and smaller towns in Tuscany, where it is used principally for motive power.

One of the 3000 kw. units has been working successfully for a year and another for nine months, the third having only been started recently.

The production of power from this source could be increased very largely in the district in question, since the region of the soffioni is known to extend for many square miles around Larderello. Near Naples, also, in the Campi Flegrei, the ground in places, at a depth of 100 feet, is very hot, and similar utilisation of this source of power is in contemplation.

Journal and Patent Literature.

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—

English.—6d. each to the Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C.

United States.—1s. each, to the Secretary of the Society, who has to furnish the U.S. Patent Office with the following data:—Patent number, date, name of patentee, and title of invention.

French.—1 fr. 05 c. each, as follows: Patents dated 1902 to 1907 inclusive, Belin et Cie., 56 Rue Ferou 8, Paris (Se.); Patents from 1908 to date, L'Imprimerie Nationale, 87, Rue Vieille du Temple, Paris.

I.—GENERAL; PLANT; MACHINERY.

Klingerite [asbestos preparation]. A. Dubosc. Cautehouc et Gutta-percha. 1916, 13, 9070—9071, 9085—9088.

KLINGERITE is the trade name of a material of German manufacture, used as a packing for steam pipe joints, for which purpose it is excellently adapted. The shortage due to the war has been extensively felt and attempts—not completely successful—have been made in France to produce a substitute. The author publishes the results of an examination—chemical and physical—of the material, with practical suggestions as to how it might be prepared in a satisfactory condition. A sample in the form of a card 3.75 mm. thick was found to consist of 15 thicknesses of a thin felt of asbestos fibre mixed with about 2% of flax threads. The asbestos was of the finest commercial quality of long fibre. Each layer appears to have been coated on both sides with an agglutinant composed of a mixture of rubber and balata with a small quantity of sulphur. By pressure the whole had been worked into a uniform and compact mass. When the packing is heated in use vulcanisation occurs, rendering it more impervious and accordingly more resistant to the destructive action of steam under pressure. The results of chemical analysis gave:—Asbestos,

80-40%; cellulose (flax), 2.21%; agglutinant, 17.16% (rubber, 5.19, balata, 11.97%); sulphur, 0.13%. The percentage of sulphur is doubtful; the author suggests the use of 5% of the weight of agglutinant. The purpose of the flax is apparently to strengthen the constituent layers of asbestos for the process of coating with the agglutinant.—H. J. H.

II.A.—FUEL; GAS; MINERAL OILS AND WAXES.

Gas coals; Weathering of —. A. H. White. American Gas Inst. J. Gas Lighting, 1916, 136, 541—544.

The author describes and gives results of tests conducted at the gas experimental station maintained by the Michigan Gas Association and the Chemical Engineering Department of the University of Michigan. The tests were made on Pittsburgh and Fairmont gas coals stored for varying periods. Open gas-pipes for the reception of thermometers were laid horizontally in the coal piles, but no heating of the coal was detected. At the end of each weathering period the top 6 inches of each pile was removed carefully, sampled, and sent to the Bureau of Mines for analysis, a sample of the whole pile being then taken. The Experimental Station commenced operations in 1911, using for the distillation tests a single clay retort which lasted 3 years and was then replaced by a sectional silica retort; the temperature of the retort was observed by an optical pyrometer. The remainder of the plant consists of a jacketed condenser, an electrical tar precipitator, a Sirocco blower acting as an exhaustor, an ammonia scrubber of the tower type, an oxide purifier, a wet station meter, and apparatus for physical and chemical examination of the final gas. Ammonia passing the scrubber is estimated at the outlet and allowance made. Results of retort tests are summarised, the author observing that the higher yield of gas in the fourth and fifth year may possibly be due to the use of the silica retort. The following results were obtained with the Pittsburgh coal:—

Duration of weathering.	Gas, cub. ft. per ton.	Candle-power.	Heating value, B.Th.U. per cub. ft.	Candle-feet per lb. of coal	B.Th.U. in gas per lb. of coal.
6 months	10,135	15.4	631	78.3	3197
1 year	9,353	17.4	645	81.3	3013
2 "	10,346	16.9	624	87.7	3217
3 "	10,373	16.3	615	84.9	3188
4 "	10,509	15.0	613	79.2	3210
5 "	11,102	15.5	620	86.2	3146

No deterioration in the quality of the coke could be noted visually. The results with Fairmont coal were very similar to those with Pittsburgh coal, the influence of the silica retort being again evident. Variations in proximate and ultimate analyses on both coals stored in air were almost all within the limit of error of analysis; the only distinct change was in coal stored under water for 4½ years, the volatile matter in this case increasing to a maximum of 2% over the mine sample. The author concludes that the changes in the coals were too small to be discovered by present methods of testing and analysis, and that gas coals of the above type can be exposed to the weather for five years (provided they do not heat in storage) and at the end of this term be entirely satisfactory gas coals.—J. E. C.

Coal; Oxidation of —. G. Charpy and M. Godchot. Comptes rend., 1916, 163, 745—747.

MEASUREMENTS were made of the changes undergone by samples of coal on exposure to the air at temperatures of 100° to 150° C. for given intervals. A diminution of weight was first observed, which is shown to be equivalent to the loss of water through evaporation. At 100° C. this loss continues for about 3 hours. A gradual increase in weight then takes place, reaching a maximum value of 3 to 5% after an interval of 2 to 3 months. This change is accelerated by increase of temperature, but at 150° C. an evolution of carbon dioxide occurs, resulting in loss of weight. This slow oxidation of coal causes a loss in its calorific value, which was found to amount to 13% in some cases. The amount of ash and volatile matter were found to be unaffected by prolonged oxidation. The results show that since this oxidation of coal can proceed under ordinary atmospheric conditions, the calorific power of different samples cannot be deduced from the content of ash and volatile matter, but that a direct calorific measurement is necessary.—J. N. P.

Benzol recovery in gas-works. D. Bagley. J. Gas Lighting, 1916, 136, 491—493.

A DESCRIPTION of the Carl Still system of recovering benzol from coke oven gases is given. The gas and absorbing oil are passed through a series of tower scrubbers in opposite directions, and the benzolised oil is treated by steam in a continuous still to produce crude benzol. The debenzolised oil is continuously returned to the scrubbers, and the crude benzol is fractionated by steam into intermediate products which are then purified and rectified. The chief difficulties which arise when applying this system in a gas-works, namely: (1) the necessity of maintaining a standard calorific value for the washed gas; (2) the need for keeping the naphthalene ratio of the absorbing oil within such limits as will prevent naphthalene passing on with the washed gas in such quantities as will give trouble; and (3) the irregularity in the make of gas, are discussed.—W. H. C.

Benzol recovery [from gas]. J. A. Wilson. J. Gas Lighting, 1916, 136, 447—449.

At the Coke Oven Plant of the Staveley Coal and Iron Co., Ltd., the gas is first washed in tower scrubbers and finally in rotary scrubbers, centrifugal pumps being preferred for feeding the wash oil. Considerable improvement in controlling the working of the plant has been secured by using meters to measure the fresh absorbing oil added to the scrubbers. A more satisfactory method of determining the amount of benzol in the gas both before and after the scrubbers is desired. Variations in the temperature of the gas, owing to deficiency of cooling water in summer and autumn, have a considerable influence on the quantity of benzol recovered, which has varied from a max-

imum of 3.03 galls. of rectified benzol per ton of dry slack in February to 2.40 galls. in September. It is very important that the debenzolised oil returned to the scrubbers should contain as little water and benzol as possible. The scrubbing space should be at least 16 cubic feet per ton of coal and the amount of oil circulated such that the benzolised oil does not contain more than 3 to 4.5% of benzol.—W. H. C.

Coal gas: Determination of light oils in — and description of still for separating the light oils from the absorbing oil. D. H. Duvall. Met. and Chem. Eng., 1916, 15, 626—627.

AFTER removal of hydrogen sulphide and naphthalene by successive treatment with sodium hydroxide and picric acid, measured quantities of gas are passed through a train of 5 or 6 bottles containing a suitable absorbent, preferably oleic acid. The light oils are then separated from this solution by distillation. The still and water-cooled worm condenser are made of copper. After raising the temperature of the benzolised oleic acid to about 100° C., steam is admitted from a separate generator, and a temperature of 180° C. is finally attained. The distillate is separated from water and subjected to dry distillation. The new distillate is saponified with sodium hydroxide to remove the last traces of oleic acid, then washed with water, dried with calcium chloride, and fractionally distilled in an Engler flask.—J. N. P.

Gasoline: Effect of temperature and the time factor in the formation of — in the gas phase at constant pressure. G. Egloff, T. J. Twomey, and R. J. Moore. J. Ind. Eng. Chem., 1916, 8, 1102—1105.

THE residue of a Pennsylvanian crude oil, after the gasoline had been removed, was subjected to temperatures of 600°, 650°, and 700° C., at a constant pressure of 150 lb., and varying rates of oil flow of 17, 23, 30, 36, 45, and 65 galls. per hour, the other conditions being similar to those described previously (this J., 1916, 1004). The amount of oil recovered decreased with increase of temperature and increased with increase of the rate of oil flow. The maximum yield of gasoline (b.pt. up to 150° C.) was 28.3% of the original oil, at 600° C. and 17 galls. per hour, but taking into account the yield of gasoline per hour and the proportion of treated oil available for re-cracking, the best working conditions were 65 galls. per hour and 650° C. with a yield of 22.1%. The specific gravity of the recovered gasoline was always higher than that of ordinary gasoline, owing to the presence of aromatic hydrocarbons. It increased with increase of temperature and decreased with increase of rate of oil flow. The minimum specific gravity of the recovered gasoline was 0.745 at 36 galls. per hour and 600° C., the yield being 19.5%. The amount of olefines ranged from 22 to 29% of the recovered oil, or 3.9—7.9% of the original oil, and the amount of oil converted into uncondensable gas and carbon ranged from about 10 to 70%. (See also this J., 1916, 1209.)—A. S.

Ozokerite from the Thrall oil field. E. P. Schoch. J. Ind. Eng. Chem., 1916, 8, 1095.

A DARK brown waxy material obtained together with crude petroleum at Thrall, Texas, has been found to consist of ozokerite of good quality. Its melting point is 79.5° C., as compared with 50°—58° C. for paraffin of the same consistency. The ceresin prepared from the Thrall ozokerite melts at 75° C., has sp.gr. 0.926—0.928, and refractive index 1.4414—1.4420 at 90° C. Its solubility in carbon tetrachloride is 3.08 grms. per 100 c.c. of solvent. It is free from paraffin, for when dissolved in chloroform and fractionally precipitated with

alcohol, the fractions all had a considerably higher refractive index than that of paraffin (1.4220—1.4275 at 90° C.).—A. S.

Gases [e.g., acetylene]: Storing of — under pressure. Acetylene Illuminating Co., Ltd., and A. Stephenson, London, Eng. Pat. 12,205, Aug. 2, 1915.

A STORAGE receptacle containing a solvent or absorbent material is subjected to a temperature low enough to enable acetylene or other gas to be dissolved or absorbed at a pressure merely sufficient to cause the gas to flow into the receptacle. The rate of flow may be augmented by an exhauster. On returning to normal temperature the gas will be at a desirable storage pressure.—J. E. C.

Gas condensers. T. A. Vanston, Bolton. Eng. Pat. 16,416, Nov. 22, 1915.

A CONDENSER for coal gas or the like consists of an outer casing, easily removed, with inner walls across two opposite sides leaving narrow vertical passages on these sides. The vertical passages lead to tubes connecting the two inner walls, and are provided with baffles so as to compel water entering at the bottom to follow a sinuous course through groups of tubes. Gas enters at the top and also follows a sinuous path in horizontal streams by reason of baffles between the inner walls, openings being left at alternate ends. The direction of these horizontal gas streams is at right angles to the direction of the cooling tubes.—J. E. C.

Converting heavier [mineral] oils into lighter oils. F. Lamplough, London. Eng. Pat. 16,830, Nov. 30, 1915.

THE vapour from a heavy oil is heated to a temperature approximately 25° to 50° C. lower than that at which fixed gas is formed or at which cracking will occur. The heated vapour is then passed over electrically heated elements maintained at a dull red heat, the resulting products being led away to suitable condensing apparatus.—J. E. C.

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Incandescence gas mantles; Recent developments in ——. E. L. Knoedler. Met. and Chem. Eng., 1916, 15, 635—639.

THE durability of incandescence gas mantles, and the maintenance of a yellowish light instead of greenish-white depends mainly on the quality of the cotton or ramie threads used for the fabric, and to the presence of a sufficiency of thoria. Regularity of fabric and the absence of loose fabric are important in preventing the development of too much resistance to the passage of the gas. A satisfactory material now used consists of viscose artificial silk. Threads of this material are thin, strong, and capable of heavier impregnation than either cotton or ramie threads. Artificial fibre also possesses the advantage of uniformity of chemical composition, diameter, and other physical properties, and gives a mantle which is more durable, is a more constant light producer, and does not undergo shrinkage.—J. N. P.

PATENTS.

Incandescence electric lamps, and method of manufacturing the same, especially applicable to the manufacture of so-called half-watt lamps or gas filled glow lamps. C. O. Bastian, London. Eng. Pat. 11,332, Aug. 5, 1915.

THE atmosphere within the lamp is rarefied and the globe then sealed, with a de-oxidising agent, such as sodium, phosphorus, etc., inside the lamp, or in a connection such as a pocket which may afterwards be removed. Heat is applied externally for a prolonged period to raise the temperature of the globe, without raising the filament or electrodes to their oxidising temperature, and the oxygen in the atmosphere is withdrawn by the agent.—B. N.

Exhausting [tungsten incandescence] lamps; Process of ——. J. T. Marshall, Metuchen, N.J., Assignor to General Electric Co., New York. U.S. Pat. 1,205,002, Nov. 11, 1916. Date of appl., Oct. 23, 1911.

THE tungsten filament and metal supports are dipped into a liquid containing phosphorus distributed uniformly through it, and then dried so as to leave a coating of phosphorus on the metal parts. The lamp is exhausted to a predetermined degree, sealed, and current is then passed through the filament to render it incandescent. The phosphorus is vaporised, and reacts with the oxygen, leaving a suitable residual atmosphere, whilst the glass of the lamp is kept below the temperature at which occluded gases and water vapour are evolved.—B. III.—TAR AND TAR PRODUCTS.

Bromination of [aromatic] hydrocarbons by means of bromine and nitric acid. R. L. Datta and N. R. Chatterjee. J. Amer. Chem. Soc., 1916, 38, 2515—2552.

THE bromination of aromatic hydrocarbons may be effected by the combined action of nitric acid and bromine, commencing in the cold, and completing the reaction by the aid of heat. The chief advantages of the method are that all the bromine used is available for bromination, the hydrobromic acid liberated being immediately re-oxidised to bromine by the nitric acid. Further the reagent is very reactive and effects a speedy and energetic bromination, proceeding to varying extents according to quantity of bromine used and the duration of the treatment. From benzene either mono- or di-bromo-derivatives were obtained. Toluene gave *o*-bromotoluene and 3,4-dibromotoluene by short treatment, and pentabromotoluene on prolonged treatment. The xylenes gave monobromoxylenes, accompanied in the case of the *o*-compound by small quantities of toluic acid, and by dibromo-derivatives with *m*- and *p*-xylenes. Prolonged action gave tetrabromocompounds. Mesitylene gave the mono-substitution product in the cold, and the tribromocompound on heating. With ethylbenzene *o*- and *p*-bromoethylbenzenes formed the chief product. As would be anticipated bromination could also be effected by means of a mixture of 40% hydrobromic acid and nitric acid (sp.gr. 1.35).—G. F. M.

Aromatic alcohols; Action of ——. on aromatic compounds in the presence of aluminium chloride. I. R. C. Huston and T. E. Friedemann. J. Amer. Chem. Soc., 1916, 38, 2527—2533.

AMONG the products of the interaction of benzyl alcohol, benzene, and aluminium chloride are diphenylmethane, produced in largest amount, and smaller amounts of *p*- and *o*-dibenzylbenzene, a compound $C_{17}H_{14}$, b.pt. 308°—316° C. at 20 mm., which is probably a tribenzylbenzene or methylene-bisdiphenylmethane, and anthracene. The yields of these products are greatly influenced by the proportions of the reagents used, an excess of benzene favouring diphenylmethane formation. Similar products were obtained from benzyl ethyl ether, benzene, and aluminium chloride, and from chloromethyl ethyl ether, benzene, and aluminium chloride. In the latter case formaldehyde is probably an intermediate product.—G. F. M.

Amines; Researches on ——. VI. Utilisation of hypochlorite colour reactions in establishing the mechanism of the action of dimethyl sulphate on aniline. N. A. Shepard. J. Amer. Chem. Soc., 1916, 38, 2507—2514.

THE interaction in benzene solution of equimolecular proportions of dimethyl sulphate and aniline does not result in the formation of a quantitative yield of the methylsulphate of monomethylaniline as stated by Werner (Chem. Soc. Trans.,

1914, 105, 2762), but reactions occur, expressed by the equations:

The main product separating out in crystalline form is thus aniline methylsulphate, and mono- and dimethylanilines are formed in lesser amount. The course of the reaction was followed by means of the hypochlorite colour reactions which the three bases give under specific conditions. In neutral solution a reddish purple coloration is characteristic of aniline, the other bases giving only insignificant yellows or browns. In faintly acid solution a deep orange-yellow is characteristic of dimethylaniline, whilst aniline and monomethylaniline both give an indigo blue, which with the former is most pronounced if the addition of hypochlorite is made last. Monomethylaniline gives its most characteristic reaction in faintly alkaline solution, when a white precipitate with a slowly developing navy blue coloration fading to yellow is produced.—G. F. M.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Celluloid; Miscellaneous vegetable fibres as raw material for——. H. Nishida. J. Ind. Eng. Chem., 1916, 8, 1096-1100.

THE author has compared loose cotton of various kinds, mercerised cotton yarn, and tissue papers prepared from various other cellulosic materials as raw material for the manufacture of celluloid. Nitration was effected with a mixed acid containing H_2SO_4 61.0-65.5, HNO_3 15.0-16.5, HNO_2 0.8-1.0, H_2O 18.0-19.0%. To obtain the same degree of nitration it was found necessary to keep the product of the temperature ($^{\circ}\text{C}$) and time of nitration (mins.) constant. The value of the constant was 1500 for cotton or relatively pure forms of cellulose, 2100 for linen and allied bast fibres, 2100 for wood and straw cellulose, and 2700 for mechanical wood pulp and other fibres difficult to nitrate. When paper thicker than corresponds to 40 grms. per sq. m. is used, a correction is made as follows:

constant $0.9\sqrt{\frac{D}{40}}$, for D 40-100 grms.

constant $>0.85\sqrt{\frac{D}{40}}$, for D 100-200 grms. per sq. m.

The characters of the celluloids obtained from the different raw materials are tabulated. From the results the author classifies the various raw materials as follows: 1st class. Unbleached mercerised cotton; tissue paper from white rags and cotton fishing nets. 2nd class. Bleached mercerised cotton; tissue from coloured rags; tissue from linen fibres. 3rd class. Papers from bast fibres; weavers' waste cotton yarn, scoured and bleached. 4th class. Bamboo tissue as free from adulteration as possible, and wet-beaten. 5th class. Chemical wood fibre, and straw, as free from knots as possible. 6th class. Mechanical wood fibre mixed with a little cotton.—A. S.

Paper making industry in South Australia; Investigation into the prospects of establishing a——. W. A. Hargreaves. Dept. Chem., S. Australia. Bull. No. 1, 1916, pp. 1-56.

THE Commonwealth of Australia depends mainly on imported paper; there is one paper mill in Victoria and one in New South Wales and there are a few millboard and strawboard mills in these two States. The imports of paper (1913) are estimated at 50,000 tons of news printings, 20,000 of ordinary printings and writings, 3000 hand-made and special papers, and 10,000 tons of wrappings; of these quantities South Australia accounts for about 10%. The total import of strawboards was 3630 tons, of which 574 tons came to South Australia. So far as can be seen there is no opening for the home manufacture of news paper in Australia, there being no considerable supplies of soft-wood timber suitable for mechanical pulp, but South Australia is favourably situated for the operation of a mill producing 5000-6000 tons per annum of fine printings, writings, and wrappings, possibly in conjunction with a straw- and millboard plant under the same control. So far as native raw materials are concerned, the staple cellulose fibre must be straw, of which over half-a-million tons is available annually in a radius of 100 miles from the principal seaport. From the points of view of labour, water supply, and sea-transport, Port Adelaide offers the most favourable site for such a mill, although not at the centre of the cereal districts; it is estimated that straw could be delivered at the mill at a price not exceeding 30s. per ton. For the manufacture of the grades of paper contemplated, the straw cellulose would have to be blended with some other materials which, apart from rags and waste papers, would have to be

imported, pending the development of supplies of home-grown cellulose pulps. Several of the possible native materials have been investigated; one of the most promising appears to be a grass, *Lepidosperma gladiatum*. Other materials, such as Marram grass, Stink wort, and the inner trunk of the Grass Tree or Yacca, are capable of treatment, but give low yields and may present economic difficulties. The large deposits of Marine Fibre (*Posidonia*) afford a material giving a high yield of cellulose but very difficult to treat, so that its exploitation for paper making seems doubtful.—J. F. B.

Recent developments in incandescence gas mantles. Knoedler. See IIb.

PATENTS.

Fabrics: Device for drying tubular —. S. Cohn, New York. Eng. Pat. 102,210, Aug. 7, 1916. (Appl. No. 11,132 of 1916.)

A TUBULAR fabric, *e.g.*, incandescence gas mantle fabric, is propelled continuously over a mandrel which passes inside the tube, stretching the fabric radially, while the feeding devices stretch it longitudinally. The mandrel is surrounded by a casing through which heated air is blown in a counter direction to the fabric in order to dry it. The mandrel may be fluted near the end where it passes into the tube of fabric and smooth for the remainder of its length. At both ends of the mandrel are constricted necks in each of which two pairs of soft rollers revolve in contact with the conical surfaces and feed the tubular fabric on to and off the mandrel.—J. F. B.

Wool, rags, cotton and other loose material: Dryers for —. M. F. Kelvin, Pittsfield, Mass., U.S.A. Eng. Pat. 102,313, Mar. 30, 1916. (Appl. No. 4715 of 1916.)

The material is fed upon a platform composed of a longitudinal series of transversely extending shelves preferably perforated and capable of movement relatively to one another lengthwise of the table, movable reciprocating shelves being arranged alternately with stationary shelves, each pair overlapping the succeeding one at a slight inclination, so that the reciprocating movement of the alternate shelves between the stationary ones causes the material to be advanced along the table while exposing it to the action of the drying air.—J. F. B.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Indian sumach. Singh. See XV.

PATENTS.

Fibrous materials: Apparatus for treating —. E. D. Jefferson, Boston, Mass. U.S. Pat. 1,204,357, Nov. 7, 1916. Date of appl. Jan. 13, 1915.

AN apparatus for treating fibrous materials consists of a horizontal cylindrical cage mounted inside a concentric cylindrical tank. The tank and the cage are each provided at one end with a removable head, so that the materials in the cage

may be emptied by opening these heads and rotating the cage. The end of the cage is normally supported by a trunnion journaled in a bearing on the removable head of the tank, and separate means are provided for supporting the free end of the cage when the removable heads of the tank and cage are removed.—F. W. A.

Bleaching, dyeing, and similar kiers; Carriages of —. Jackson and Bro., Ltd., Bolton, and J. Edge, Fleetwood. Eng. Pat. 102,351, July 13, 1916. (Appl. No. 9853 of 1916.)

Bleaching apparatus: Electrolytic —. J. F. Webb and W. W. Williams. Fr. Pat. 479,902, Oct. 1, 1915. SEE Eng. Pat. 20,711 of 1914; this J., 1915, 1139.

Printing on fabrics, etc.; Machines for —. H. D. Herring and H. Harrison. Fr. Pat. 481,141, Mar. 9, 1916.

SEE Eng. Pat. 1411 of 1915; this J., 1916, 251.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Sulphuric acid: Maximum prices for sales of —. Ministry of Munitions, Dec. 30, 1916.

THE Minister of Munitions has cancelled the figures for maximum prices for the sale of sulphuric acid given in previous circulars (see this J., 1916, 251) and substituted the following, which refer to sales of sulphuric acid of all descriptions and for all purposes, unless expressly excepted:—

		Maximum price per ton for acid delivered into tank wagon, cart or barge at makers' works.
Class A.—Arsenical acid	140° Tw. at 60° F.	70/—
Class B.—Non-arsenical or de-arsenicated ..	144° Tw. at 60° F.	85/—
Class C.—Arsenical ..	95% H ₂ SO ₄	130/—
Class D.—Non-arsenical or de-arsenicated ..	95% H ₂ SO ₄	110/—

With regard to sales of acid of strengths other than those given above, the Minister recommends that the following adjustments in price should be made:—

Classes A and B comprise acid containing 90% or less H₂SO₄.

In the case of acid in Class A, an adjustment of fivepence per degree Twaddell should be made in respect of each complete degree by which the specific gravity differs from 140° Tw., at 60° F.

In the case of acid in Class B, an adjustment of sixpence per degree Twaddell should be made in respect of each complete degree by which the specific gravity differs from 144° Tw., at 60° F.

Classes C and D.—All acid of over 90% H₂SO₄ is contained in these classes. Payment should be made on the basis of percentage of monohydrate in each consignment. The following scales for payment are recommended:—

	Arsenical.	De-arsenicated or non-arsenical.
Over 90% and up to 91%	£ s. d.	£ s. d.
Over 91% and up to 92%	5 3 0	5 13 0
Over 92% and up to 93%	5 9 0	5 19 0
Over 93% and up to 94%	5 15 0	6 5 0
Over 94% and up to 95%	6 1 0	6 11 0
Over 95% and up to 96%	6 4 0	6 14 0
Over 96% and up to 97%	6 7 0	6 17 0
Over 97% and up to 98%	6 10 0	7 0 0
Over 98% and up to 99%	6 15 0	7 5 0
Over 99% and up to 99%	7 0 0	7 10 0
Over 96, in both cases, an additional 1/- for each complete %.		

Packages. 1. When the acid maker supplies the railway tank wagons he shall be entitled to make a further charge of not more than 5s. per ton for filling and hire of such wagons. 2. When the acid maker supplies the acid in his own drums he shall be entitled to make a further charge of not more than 10s. per ton for filling and hire of drums. When drums are supplied by the purchaser a charge of 2s. per ton may be made to cover the cost of filling. 3. When the acid is supplied in the acid maker's own carboys he shall be entitled to make a further charge of £1 per ton for filling and hire of carboys. When carboys are supplied by the purchaser a charge of 5s. per ton may be made by the acid maker, to cover the cost of filling.

Notes. 1. The maximum prices apply to sales of sulphuric acid made by sulphuric acid makers and their agents, but not to sales by dealers and merchants who are themselves not makers of sulphuric acid. 2. Merchants and dealers will be required to furnish a monthly return of sales (of sulphuric acid) made by them, setting out the prices charged in each instance. 3. The maximum prices do not apply to exports of sulphuric acid under permit to persons, companies or firms abroad, nor do they apply to the sale of sulphuric acid imported from abroad. 4. The maximum prices do not apply to the sale of sulphuric acid made wholly from brimstone, or to sulphuric acid specially purified for laboratory purposes. 5. In cases where a maker of sulphuric acid has, in order to supply his customers, to purchase supplies of acid from a third party, it will be permissible for him, in so far as this is a departure from his normal procedure, to charge to his customers any extra cost of carriage thereby incurred.

The above maximum prices came into force on the 1st January, 1917.

Sulphur in pyrites: Results of co-operative work on the determination of —. H. C. Moore. J. Ind. Eng. Chem., 1916, 8, 1167—1170.

THE results obtained in 25 different laboratories by three different methods are tabulated and discussed. Allen and Bishop's method (this J., 1912, 919) gives much more concordant results than Lunge's method, and is recommended as an accurate method for the determination of sulphur in pyrites. It has been modified as follows to allow of using a smaller sample: 0.5495 gm. of the powdered sample, dried at 100° C., is treated with 6—8 c.c. of a mixture of 2 parts of bromine and 3 parts of carbon tetrachloride by volume, and left for 15 mins. in a tall covered beaker, with occasional shaking; 10 c.c. of concentrated nitric acid is then added and after standing for 15 mins., with occasional shaking, the mixture is heated below 100° C. until most of the bromine has been expelled, and then evaporated to dryness on a steam plate. The residue is treated with 10 c.c. of concentrated hydrochloric acid, the mixture evaporated to dryness, and the residue heated at 100° C. for $\frac{1}{2}$ —1 hour to dehydrate the silica, and then moistened with 1 c.c. of concentrated hydrochloric acid and heated with 50 c.c. or more of water until solution is complete. After cooling for 3—5 mins., 0.1 gm. of powdered aluminium is added and when reduction is complete the solution is filtered, and the residue washed nine times with hot water. The solution is treated with 2.5 c.c. of concentrated hydrochloric acid, then diluted to 650 c.c., and 50 c.c. of cold 5% barium chloride solution added slowly, without stirring, preferably in single drops at the rate of about 5 c.c. per minute. The mixture is stirred, allowed to stand for at least 2 hours, and the precipitate collected on a thick layer of asbestos in a Gooch crucible, using suction. After washing with cold water, the precipitate is dried and ignited.

Smoot's method (this J., 1912, 918) also gives good results but possesses no advantage over the above process and requires special apparatus. —A.S.

Potash from kelp in the United States. Board of Trade J., Dec. 14, 1916.

A PLANT on a commercial scale is to be set up by the United States Department of Agriculture for the conduct of experimental work in the production of potash from kelp, an appropriation of 175,000 dols. (about £36,000) having been made for this purpose. It is expected that the plant will be established in Southern California, either at Santa Barbara or Long Beach, and that constructive work will be begun soon after the site has been decided upon. The plans are for a plant capable of dealing with approximately 200 tons of wet kelp per day. The equipment will consist of drying kilns, distilling chambers, vats, handling machinery, etc. Electric power will probably be used for all mechanical operations, while heat for drying and distillation will be furnished by the use of crude petroleum. From the 200 tons of kelp treated daily about 5 tons of muriate of potash will be manufactured. The primary purpose of the plant will be to determine the most economical processes for producing potash from kelp and to work out methods for the recovery and utilisation of by-products. Numerous methods will be employed experimentally, but for the most part the Department of Agriculture will rely on distillation processes.

The area of the kelp beds along the United States Pacific coast is nearly 400 square miles. From this area, it is officially estimated, the annual cuttings, including two cuttings per annum off the coast of south-western California, would yield 59,000,000 tons of kelp from which 2,300,000 tons of potassium chloride could be produced.

Alunite deposits in Vancouver. C. H. Clapp. Bull. Imp. Inst., 1916, 14, 483—484.

A DEPOSIT of alunite at Kyuquot Sound, Vancouver, has been found to cover an area of 4½ acres and is estimated to contain 600,000 tons above sea-level. The rock contains 20—45% of alunite, 40—50% of quartz, up to 14% of sericite, a little diaspore, and usually some pyrite. Analysis of two samples showed 4.4 and 2.4% K₂O, and indicated that the alunite is of the sodic type. It is doubtful whether the deposit will prove to be of economic value as a source of alum.

Potassium chlorate: [Electrolytic] manufacture of —. A. G. Betts. Met. and Chem. Eng., 1916, 15, 627.

THE oxidation of potassium chloride to chlorate by electrolysis is determined largely by the nature of the materials of the electrodes. With most metals, a serious loss of the product results through reduction at the cathode. By using platinum electrodes and a small quantity of a soluble chromate in the electrolyte, as in the process of Inhoff, a very high current efficiency is obtained. A process devised by the author (U.S. Pat. 918,650 of 1909; this J., 1909, 529) for treating alkali chlorides obviates the use of platinum by employing carbon anodes and magnesium cathodes. A coarse diaphragm is preferably used so as to hinder the intermixing of anode and cathode liquors. The acid anolyte and alkaline catholyte thus obtained favour the preservation of the electrodes, while the conversion of hypochlorite into chlorate is accelerated, and the evolution of oxygen depressed, through the presence of acid in the anode liquor. The raw material used is felspar, which is ground, treated with lime, and lixiviated. The mixed chlorides are electrolysed and the potassium chlorate crystallised out. By using water power, potassium

chlorate can, in this way, be produced at the present time, at a cost of 6 to 7 cents (3-3½d.) per pound.—J. N. P.

Thiocyanates; Detection of —. L. J. Curlman and B. R. Harris. J. Amer. Chem. Soc., 1916, **38**, 2622-2629.

THE reaction between ferric chloride and a thiocyanate is a very sensitive test for iron but not so for thiocyanates, since the maximum coloration depends on the presence of an excess of thiocyanate. Moreover, arsenates, phosphates, tartrates, fluorides, and borates interfere with the reaction, ferrocyanides mask the red colour, and iodides, acetates, and nitrates yield colorations with ferric chloride similar to that given by a thiocyanate. A method recommended for the detection of thiocyanates depends on the fact that silver iodide is not attacked by hot 5% sodium chloride solution, whilst silver thiocyanate is converted into silver chloride and sodium thiocyanate by this treatment. The solution to be tested is rendered just alkaline with sodium hydroxide, then barium nitrate, calcium nitrate, and cobalt nitrate are added in excess in the order given (this treatment removes sulphides, cyanides, ferrocyanides, and other interfering substances), the mixture is boiled, 3 grms. of washed asbestos is added, and the solution filtered. The filtrate is acidified with nitric acid, silver nitrate is added, the mixture boiled, and the precipitate collected on a filter. The precipitate is washed, then boiled for 5 minutes with 10 c.c. of 5% sodium chloride solution, filtered, the filtrate evaporated to 4 c.c., acidified with a drop of 10% nitric acid and treated with 0.5 c.c. of 2N ferric nitrate solution. The coloration obtained does not afford a means of determining the quantity of thiocyanate present, especially in the case of relatively large amounts; between 25 and 250 mgrms. of thiocyanate there is no appreciable difference in the coloration. The quantity of mercuric chloride solution required to change the red colour to a definite brown tint furnishes, however, an approximate measure of the thiocyanate.—W. P. S.

Fluorine in soluble fluorides; Determination of —. J. G. Dinwiddie. Amer. J. Sci., 1916, **42**, 464-468.

A NEUTRAL solution of the fluoride is heated to boiling and powdered calcium sulphate is added; after standing for 1 hour, with frequent stirring, the precipitate, consisting of calcium sulphate and calcium fluoride, is washed several times by decantation and then collected on a filter. The latter consists of a disc of filter-paper fitted into the bottom of a perforated platinum crucible. The precipitate is now washed (the wash-water used should be saturated previously with calcium sulphate and calcium fluoride), then rinsed into an ordinary platinum crucible and the water evaporated; the disc of filter paper is, meanwhile, ignited on the crucible lid and the ash introduced into the crucible. The dry contents of the crucible are then heated at 300° C. for 1 hour, or until constant in weight, then sulphated, again heated at 300° C., and weighed. The increase in weight after sulphating is due to the replacement of two atoms of fluorine by the sulphuric acid radicle, and a simple calculation gives the quantity of fluorine present. The error of the method is about 0.1%.—W. P. S.

Perchlorates, periodates, persulphates, percarbonates, and perborates; Reactions for distinguishing between —. A. Monnier. Ann. Chim. Analyt., 1916, **21**, 237-240.

THE following reactions are given for the detection and identification of per-salts in aqueous solution, but the latter must be free from heavy metals,

vanadates, tungstates, molybdates, bichromates, and ferricyanides. *Perborates and percarbonates.* These salts give the general reactions for boric acid, carbon dioxide, and hydrogen peroxide. To detect their presence when mixed with borates and carbonates, a portion of the solution is treated with dilute potassium bichromate solution acidified with sulphuric acid; a blue coloration indicates that a percarbonate or perborate is present. To identify a perborate, a solution of chrome alum is treated with an excess of the solution to be tested, ether and dilute sulphuric acid are added, and the mixture is shaken gently; the ethereal layer is coloured blue. Percarbonates and hydrogen peroxide do not give this reaction. *Iodates and periodates.* To the solution is added a small quantity of chloroform and then titanium trichloride solution; a white precipitate is formed and iodine is liberated, giving a violet coloured solution with the chloroform. Titanium trichloride also liberates iodine from potassium iodide in the presence of chlorates or perchlorates, but in this case a white precipitate is not produced. The reaction with silver nitrate serves to distinguish periodates from iodates. If an alcoholic solution of benzidine is poured on the surface of the solution under examination, a brown zone appears in the presence of periodates but not with iodates. *Chlorates and perchlorates.* A portion of the solution is shaken with the addition of potassium bromide, chloroform, and titanium trichloride solution; chlorates liberate bromine and this gives a brown chloroform solution, but perchlorates do not give the reaction. Another portion of the solution is treated, drop by drop, with a 0.2% Methylene Blue solution; a violet precipitate, which detonates when heated on a piece of platinum foil, indicates the presence of a perchlorate. In testing for chlorates and perchlorates, iodides, if present, must be removed previously by treatment with silver oxide, and iodates and periodates by means of silver nitrate, the excess of the latter being then removed by the addition of potassium bromide. *Detection of bromates in the presence of chlorates and iodates.* To the solution is added manganous sulphate solution acidified with sulphuric acid; in the presence of a bromate, the solution is coloured violet, owing to the formation of manganic sulphate, and bromine is liberated. This reaction is not given by chlorates or iodates. *Persulphates.* In the absence of iodides and perchlorates, a rose-red precipitate is obtained when a persulphate is treated with Methylene Blue solution. Persulphates may be identified in the presence of perchlorates by pouring an alcoholic benzidine solution on the surface of the solution to be tested; a blue zone at the junction of the two liquids denotes the presence of a persulphate. A 2% aniline solution may be used in place of the benzidine solution.—W. P. S.

Oxidation-reduction reactions without the addition of acid. III. Ferrous chloride and potassium permanganate. A method for the preparation of colloidal hydrated ferric oxide. M. Neidle and J. N. Crombie. J. Amer. Chem. Soc., 1916, **38**, 2607-2613. (See also this J., 1915, 1089; 1916, 253.)

THE same stoichiometric relations obtain in the permanganate-ferrous sulphate and permanganate-ferrous chloride reactions whether or not acid is added. In the latter reaction the oxidation of the chloride ion is practically prevented by adding the permanganate gradually while the mixture is stirred; the products of this reaction are potassium, manganese, and ferric chlorides, and colloidal hydrated ferric oxide, whilst in the permanganate-ferrous sulphate reaction the corresponding sulphates are formed together with hydrated ferric

oxide which is precipitated by the sulphate ion. When 1 gram.-equivalent of permanaganate, dissolved in 600 c.c. of water, is added slowly to 1 gram.-equivalent of ferrous chloride, dissolved in 1 litre of water, and the resulting deep brownish-red solution diluted to 2 litres, the latter remains clear for several weeks, then gradually becomes more and more turbid, and a precipitate settles. Until the latter stage is reached, dialysis yields a perfectly clear brownish-red hydrosol of hydrated ferric oxide; after the precipitate has settled out, dialysis gives a hydrosol of hydrated ferric oxide which is slightly turbid in reflected light but clear in transmitted light.—W. P. S.

Calcium tartrate; Crystallisation of—. F. D. Chattaway. J. Amer. Chem. Soc., 1916, 38, 2519—2522.

WHEN a soluble calcium salt is added to a neutral solution of a soluble tartrate the compound which first separates, in fine needles if the solutions are sufficiently dilute ($N/5$ or less), is a hexahydrate. This is unstable at the ordinary temperature and is transformed even when in contact with water into the denser orthorhombic tetrahydrate, small crystals of which quickly appear amongst the needle-shaped crystals and grow at their expense. The change is much accelerated on warming.

—G. F. M.

Dehydration of some crystalline hydrates; A period of induction in the—. W. N. Rae. Chem. Soc. Trans., 1916, 109, 1229—1236.

AN initial period of induction in the dehydration of crystalline hydrates, during which the weight remains sensibly constant, has been previously observed, and certain of the determining conditions have now been investigated using copper sulphate pentahydrate and dehydrating over sulphuric acid. The state of division made no difference in the period of induction, which lasted about two days, after which a rapid loss of about 2 mols. of water occurred before the dehydration finally slowed down. The induction period was absent when specimens re-hydrated in the air were used, when the material was mechanically stirred, and also when it was inoculated with at least 1% of the trihydrate. On the other hand the induction period was lengthened by using copper sulphate crystallised from a dilute gum arabic solution, and by a reduction in temperature. Similar results were observed with other crystalline hydrates, and the theoretical aspect of the phenomenon is discussed, but no explanation is offered which can account for all the results.—G. F. M.

Tellurium; Behaviour of — towards hydrogen peroxide. G. Schluck. Monatsh. Chem., 1916, 37, 489—494. J. Chem. Soc., 1916, 110, ii., 615.

THE behaviour of tellurium towards hydrogen peroxide is found to depend on the physical condition of the element. Colloidal tellurium is acted on by very dilute solutions of the peroxide, whilst the crystalline modification only reacts slowly with 60% hydrogen peroxide at 100° C. The rate of dissolution increases with the amount of telluric acid formed. Amorphous tellurium, precipitated from hydrochloric acid solution by sulphur dioxide and dried at 105° C., behaves similarly to crystalline tellurium, but if the amorphous variety is dried by treatment with alcohol and ether, it dissolves quite readily in concentrated hydrogen peroxide solutions.

PATENTS.

Electrolytic cells [for decomposing nitrates]. H. C. Jenkins, and C. I. (1914) Syndicate, Ltd., London. Eng. Pat. 16,643, Nov. 25, 1915.

AN electrolytic cell of the bell type (see Eng. Pat. 25,415 of 1913; this J., 1914, 1906), for the decomposition of nitrates, is arranged so that the electrodes almost fill the interior of the bells, and the electrolyte within the bells is maintained under a reduced pressure. A high current density is employed, and each of the bells is heated externally by superheated steam or by other suitable means.—B. N.

Calcium cyanamide; Production of—. G. Tofani, Rome. Eng. Pat. 14,662, Oct. 16, 1915.

IN the production of calcium cyanamide from calcium carbide and air or nitrogen, the latter is purified by making it traverse a layer of filtering material, e.g., sand, quick-lime, carbon, bricks, asbestos, or layers of wire cloth or net of small mesh. The filter may surround and be in contact with the calcium carbide, or it may be placed in the tubes which supply the nitrogen.—E. H. T.

Calcium cyanamide; Process for the production of—. G. Tofani, Rome. Eng. Pat. 14,663, Oct. 16, 1915.

IN the manufacture of calcium cyanamide from calcium carbide and nitrogen, the reaction is started by embedding in the mass of pulverised carbide a freshly cast and still incandescent ingot of the carbide.—F. SODN.

Sodium perborate; Electrolytic production of—. Deutsche Gold- u. Silber-Scheideanstalt, vorm. Roessler, Frankfurt, Germany. Eng. Pat. 102,089, Mar. 1, 1916. (Appl. No. 3099 of 1916.) Addition to Eng. Pat. 100,152 (this J., 1916, 1261).

THE cathodes composed of iron, copper, or other materials with a hydrogen potential practically equal to zero, are protected by metallic nickel at the points of exposure to the electrolytic liquid and air.—E. H. T.

Active oxygen; [Alkali perborate] compound containing — and process of making same. O. Liebknecht, Frankfurt, Germany, Assignor to The Roessler and Hasslacher Chemical Co., New York. U.S. Pat. 1,200,739, Oct. 10, 1916. Date of appl., Dec. 24, 1913.

AN alkali perborate is combined with the carbonate of a "basic metal" other than an alkali metal. For example, an alkali carbonate is generated in a mixture yielding an alkali perborate, and the mixture is then allowed to react with a soluble compound of an alkaline-earth metal. The product is claimed to be stable.—F. SODN.

Limckiln. A. Zimmerman, York, Pa., Assignor to L. M. Palmer, Brooklyn, N.Y. U.S. Pat. 1,199,856, Oct. 3, 1916. Date of appl., Feb. 25, 1915.

A STACK, divided into feed, combustion, and discharge zones, has a number of gas inlets around the surface of the inner wall, on a level with the bottom of the burning zone, and a number of air

inlets entering the discharge zone at spaced intervals around its inner face and spaced from and beneath the gas inlets. The combustion and discharge zones are preferably divided into chambers into which gas and the main portion of air are introduced as above, whilst the discharge zone has an opening at the bottom through which also air may enter the stack; the air inlets, which may be open to the atmosphere at their outer ends, should not be in vertical alignment with the gas inlets.—F. SODX.

Line: Process and apparatus for hydrating—.

A. M. Schofield, Amherst, Ohio, U.S. Pats. (A) 1,204,699 and (B) 1,204,700, Nov. 14, 1916. Dates of appl. (A) Jan. 31 and (B) June 12, 1916.

(A) QUICKLIME is slaked in a container, through which the materials are passed at a uniform speed. The steam evolved near the intake end is retained under pressure, and that evolved near the outlet is led away and used for heating the water that is required for further slaking. (B) The container is furnished with means for admitting lime and water and for discharging the slaked product. A heat-retaining jacket is placed on the container near the intake end, and a water jacket, fitted with inlet and exit pipes, on the other end.—E. H. T.

Bleaching powder: Machine for making—.

I. Ishikawa, Tokio, Japan, U.S. Pat. 1,200,499, Oct. 10, 1916. Date of appl. Jan. 8, 1916.

A SERIES of superposed tubes, communicating with each other at opposite ends, is provided with means for introducing lime into the top tube and causing it to travel through each tube in succession, in opposition to a current of gas which is admitted into the bottom tubes. The bottom tube is fitted with a device for sifting the product, and there are means for filtering the gas which has passed through the tubes. The tubes are preferably arranged in sets of three, and mounted in each tube is a shaft with agitators and scrapers (adjacent the ends of the tube), the shafts of each set being rotated by chains actuated from a common source.—F. SODX.

Alkali-metal [potassium] compound from silicates [felspar]: Process of obtaining—.

W. A. Schmidt, Assignor to International Precipitation Co., Los Angeles, Cal. U.S. Pat. 1,200,887, Oct. 10, 1916. Date of appl. Feb. 18, 1915.

THE mineral is heated in the presence of an alkaline earth (e.g., lime) and of hot gases, preferably containing sulphur dioxide, so as to volatilise and carry off potassium compounds, which are then condensed and precipitated by cooling the gases sufficiently and subjecting them to the action of an electric field; or, the gases may be subjected to a series of successive precipitating actions in electric fields, in order to throw down dust and other suspended impurities before precipitating the particles of potassium compounds.—F. SODX.

Ammonia: Process of hydrogenating organic materials and of producing—.

C. Ellis, Montclair, N.J., U.S. Pat. 1,201,226, Oct. 10, 1916. Date of appl. July 1, 1914.

THE material to be hydrogenated is treated with a gas containing hydrogen, in presence of a catalyst which contains a hydrogen-occluding metal, such as nickel, and a nitrogen-occluding solid non-metallic element capable of forming a hydride, e.g., boron, parts at least of the metal and non-metal being chemically combined with each other. Ammonia is produced by bringing nitrogen and hydrogen into contact with such a catalyst.

—F. SODX.

Liquefaction and rectification of air: Apparatus for the—.

H. Filippo, jun., P. Schoonenberg, and Naamlooze Vennootschap Philips' Metaal-Gloeilampenfabriek, Eindhoven, Holland, Eng. Pat. 101,860, Jan. 20, 1916. Under Int. Conv., Oct. 16, 1915. (Appl. No. 949 of 1916.)

COMPRESSED air, cooled by passing through a heat-exchanger, is passed downwards through a tubular rectifying column and a bath of boiling oxygen situated at the base. The liquefied air flows over into a higher part of the column the interior of which consists of an inner column or chamber provided with bubbling devices and draw-off pipes at various levels. In this chamber the oxygen containing argon is separated into a purer oxygen and a gas rich in argon which can be used for filling electric lamps.—E. H. T.

Oralic acid: Process of producing—.

E. von Portheim, Prague, Austria-Hungary, U.S. Pat. 1,205,493, Nov. 21, 1916. Date of appl. Mar. 27, 1916.

SEE Eng. Pat. 14,234 of 1915; this J., 1916, 889.

Chlorates of alkali metals: Manufacture of—.

A. E. Gibbs, Wayne, Pa., U.S.A., Eng. Pat. 13,452, Sept. 21, 1915. Under Int. Conv., May 5, 1915.

SEE U.S. Pat. 1,173,346 of 1916; this J., 1916, 469.

Alkali chlorates and perchlorates: Manufacture of—.

A. E. Gibbs, Fr. Pat. 479,833, Sept. 25, 1915.

SEE U.S. Pat. 1,173,346 of 1916; this J., 1916, 469.

Electrolytic apparatus for producing solutions for bleaching and other purposes—.

A. Holliday and G. E. Ward, Fr. Pat. 480,451, Dec. 15, 1915.

SEE Eng. Pat. 1672 of 1915; this J., 1915, 622.

Phosphorus sulphides: Process for producing—.

Fr. Pat. 479,992, Oct. 13, 1915.

SEE U.S. Pat. 1,153,051 of 1915; this J., 1915, 1055.

VIII.—GLASS; CERAMICS.

Optical glass: A precision method of uniting—.

The union of glass in optical contact by heat-treatment. R. G. Parker and A. J. Dalladay, Faraday Soc., Dec. 18, 1916. [Advance proof.] 8 pages.

THE cements available for uniting pieces of glass in the construction of cells and optical instruments have numerous defects. These can be wholly avoided by accurately cutting and polishing the two glass surfaces which it is desired to unite, placing them in optical contact under moderate pressure, then heating them very slowly to about 70°–80° C. below the true annealing temperature of the glass (e.g., to 150°–550° C.) and keeping them at this temperature for 1½ hours or longer. Glasses of different composition unite perfectly if their annealing temperatures do not differ by 50° C. The annealing temperature is ascertained by placing a piece of the glass having two plane, parallel and polished sides in an electric furnace and observing the temperature at which the strain caused by unequal heating (rendered visible by changes in the intensity of polarised light transmitted through the glass) disappears. When this process of uniting glasses is used all the optical surfaces remain quite free from deformation, little internal stress is observable, and almost perfect parallelism between the sides of glass cells can be readily secured. When the pieces are properly united and force is applied to separate them, pieces of one are removed with the other and a crack or cut spreads through the two pieces as through one piece of glass. Rayleigh cells and polarimeter tubes, of soda-lime glass, with windows

of plate glass, produced by this process are convenient on account of ease of cleaning and freedom from corrosion. The process appears to be equally applicable to articles made of fused silica, the annealing temperature of this material being about 1100°C .—A. B. S.

Refractories; A carbon tube furnace for testing the softening points and compressive strengths of —.

E. and E. A. Griffiths. Faraday Soc., Dec. 18, 1916. [Advance proof.] 9 pages.

THE furnace described has a vertical carbon tube 2 in. outside diam., $1\frac{1}{2}$ in. inside diam., and 11 in. long, with a longitudinal slot, $\frac{1}{4}$ in. wide, for observation purposes, extending the whole distance between the electrodes. This tube is surrounded by a cylinder of crude zirconia and the latter by one of magnesia-asbestos lagging, 3 in. thick. A sheet-iron casing 12 in. diam. with end-plates of asbestos slate boards encloses the whole. Pressure up to 150 lb. per sq. in. may be applied to the test-piece by means of two spiral springs of equal length attached to a cross bar which can be screwed up and down by a handwheel. These springs act on the cross-head of a vertical plunger which applies the pressure to a small carbon rod lying on the test-piece. The amount of pressure is shown by a vertical scale. The electrodes are made by bending a copper tube into a zig-zag form for each half electrode, fitting this into a mould made of sheet iron with the carbon cylinder of the electrode as a core, and pouring in white bearing metal so as to fill in the intervening space and so produce a casting which gives perfect contact between the copper cooling tube to which the electric cables are attached and the carbon tube. One of the electrodes must have sufficient flexibility to enable the carbon tube to expand and contract freely. The furnace is heated by an alternating electric current of about 350 amps. The test-piece is a cylinder, $\frac{5}{8}$ in. diameter and 1 in. long, made by grinding a piece of the sample to the required size and shape. It is supported on a carbon rod. During observations a current of nitrogen is passed through the furnace to ensure freedom from dust and fog and a neutral atmosphere. A temperature of 3000°C . can be maintained for short periods, but above 1700°C . it is impossible to avoid particles of carbon being shot off the tube on to the test-piece. The temperatures were estimated by matching the light from the test-piece with that from a lamp through which a constant current was passed. Bibliographies on electric furnaces, the melting points and softening points of refractory materials under load, and products of electric furnaces are given.—A. B. S.

IX.—BUILDING MATERIALS.

Portland cement; Slow volume changes in —.

E. D. Campbell. J. Ind. Eng. Chem., 1916, 8, 1101—1102.

SOME of the test-bars used in a previous investigation on the effect of free lime and magnesia on the constancy of volume of Portland cement (see this J., 1906, 1097) have been kept under water for further periods, extending in some cases up to 13 or 14 years, and then again examined. The results are tabulated. They confirm the conclusions previously drawn as to the injurious effect of free magnesia. Attention is drawn to two test-pieces, both containing about 7% total magnesia, but one somewhat more finely divided and with a lower basic ratio than the other. The more finely divided cement passed all the ordinary tests

and even after immersion for 13—14 years had not expanded to any extent likely to be dangerous, but the other cement—similar to the first except that it had a slightly higher basic ratio (280:2 mols. CaO as against 270:7 mols. CaO per 100 mols. SiO_2) and was somewhat coarser—gave very nearly double the amount of expansion after the first year. If raw material high in magnesia is used, much greater care in manufacture is required to obtain a satisfactory product than when purer raw material is used.—A. S.

Cresote oils [for wood preservation]; Relation between toxicity and volatility of —. E. Bateman. J. Ind. Eng. Chem., 1916, 8, 1094—1095.

DIFFERENT coal-tar cresotes and water-gas tar cresotes were tested as to their toxicity against *Fomes annosus*, and it was found that if the

toxicity (per cent. required to kill the organism under definite conditions) be plotted against the volatility (per cent. distilling below 275°C .), two regular curves are obtained (see fig.). The relationship between the toxicity and volatility is so regular that if the authenticity of an oil is without question, its toxicity can be predicted accurately from the result of a distillation test. The results indicate that the toxicity of coal-tar cresote is largely due not to hydrocarbon oils and solids but to high-boiling tar acids and bases; and that it might be possible to determine the purity of tar oils by some such test as the Rideal-Walker test on the high-boiling fractions.—A. S.

PATENTS.

Cement or hydraulic lime; Manufacture of —. L. P. Basset, Montmorency, France. Eng. Pat. 22,614, Nov. 17, 1911. Under Int. Conv., Nov. 18, 1913. Addition to Eng. Pat. 17,873, Mar. 4, 1913.

SEE Addition of Nov. 18, 1913, to Fr. Pat. 466,518 of 1913; this J., 1915, 1091.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Sulphur in iron and steel; Determination of —.
H. B. Pulsifer. J. Ind. Eng. Chem., 1916, 8, 1115—1123.

THE methods for the determination of sulphur in iron and steel are classified and discussed, and a bibliography covering 285 original articles dating from 1797 onwards is given. The effect of the segregation of sulphur in the metal is emphasised and it is shown that the material used for analysis should be capable of passing an 80-mesh screen in order to correct the effect of segregation. The author has compared the method of oxidising with nitric acid, Bamber's method (this J., 1894, 665), and the chloric acid method (this J., 1901, 1162) on 22 samples ranging from 0.008 to 0.25% S, making in all 238 determinations. The nitric acid method gives good results, and it was found that moderate amounts of hydrochloric acid do not appreciably increase the solubility of barium sulphate in the ferric chloride solution. Bamber's method is liable to give high results, but if carried out in a special laboratory free from dust and fumes, the results agree almost exactly with those obtained by the nitric acid method. The chloric acid method usually gives results intermediate between those furnished by the other two methods and has the advantage that it is possible to precipitate the barium sulphate in 20 minutes from the time the sample is weighed out.—A. S.

Iron: Do equiatomic solutions in — possess equal resistances? E. D. Campbell. Faraday Soc., Dec. 18, 1916. [Advance proof.] 8 pages. (See also this J., 1916, 1018.)

INVESTIGATION was made with very pure basic open-hearth, hypoeutectoid and eutectoid steels, the specific resistances of which were determined after quenching, tempering, and annealing. The values found differed considerably from those calculated by means of Benedicks' formula (this J., 1902, 1031), and the differences were inexplicable on the assumption that equiatomic concentrations of carbon produce equal effect on the specific resistance. From the results obtained, and by analogy with aqueous solutions, it is suggested that equimolecular concentrations of carbides in solution exert equal influence on the specific resistance of steels. The results are regarded as confirming Benedicks' assumption that the total specific resistance of steel is made up of two components, due to the solvent and solute respectively; and as indicating almost conclusively that the increase in specific resistance with increased temperature of measurement is due almost entirely to the increase in specific resistance of the solvent, that of the solutes in solid solution being very slightly, if at all, affected by temperature.—W. E. F. P.

Steel: Grain-growth in deformed and annealed low-carbon —. R. H. Sherry. Faraday Soc., Dec. 18, 1916. [Advance proof.] 15 pages.

THE formation of coarse grains in low-carbon steels occurs after limited permanent deformation and subsequent annealing within certain temperature ranges. In the present investigation, various commercial low-carbon steels were subjected to forging, hot rolling, cold drawing, cold pressing, etc., and then examined for size of grain; the amounts of deformation were measured by determining the reduction of area in each case. The deformation limits within which grain growth occurred were found to correspond to reductions of area between about 7 and about 25—30%; and

the annealing range to be 650—900° C. Within these limits, the greater the strain imposed the smaller was the grain size produced by annealing; but when the strain was less than a certain or "critical" amount (corresponding to a reduction of area of about 9%), the annealing range within which the grain growth occurred appeared to be limited by thermal critical points at about 690° and 780° C. Grain growth was suppressed by the presence of carbon, this effect being very pronounced in steels containing 0.15% C, although negligible in those of very low carbon content; no appreciable grain growth occurred in steels containing above 0.18% C.—W. E. F. P.

"Invar": Modifications in the dilatibility of — produced by mechanical and thermal treatment. C. H. Guillaume. Comptes rend., 1916, 163, 651—658.

FOR commercial uses, "invar" (a nickel steel containing approximately C 0.5, Mn 0.5, Ni 36%) is usually rolled at a cherry-red heat and cooled in air. The present investigation was made to determine the effects of annealing, quenching, and cold working on the dilatibility of the alloy as ordinarily supplied. The coefficient of expansion was increased by annealing for several hours at 900° C. and cooling in air or in the furnace, and decreased by quenching in water, the range of variation from these causes being 1.18×10^{-6} . By cold drawing the annealed or quenched alloy, the dilatibility was rapidly decreased, the combined effects of the thermal and mechanical treatments being to reduce the original coefficient of expansion by 2.18×10^{-6} . The dilatibilities of quenched rods and cold drawn wires, already 0.49×10^{-6} and 1.50×10^{-6} below that of the alloy as commercially supplied, were increased by 0.42×10^{-6} and 0.80×10^{-6} respectively, by prolonged heating at temperatures up to 250° C.; whereas the dilatibility of the alloy in the "natural" (as supplied) or annealed condition was scarcely affected by this treatment. From the results obtained it is concluded that the effect of cold drawing on the dilatibility of commercial "invar" is practically neutralised, and the alloy stabilised as far as geodetic requirements are concerned, by prolonged heating at 100° C.—W. E. F. P.

Copper: Restrictions on the use of and dealing in —.

THE Minister of Munitions has made the following Orders under date 8th December:—

A.—Restrictions on the use of copper. The use of copper, whether wrought or unwrought, in any kind of manufacture is prohibited, except for the purposes of a contract or order for the time being in existence certified to be within Classes "A" or "B" of Circular L 33 as to control of output issued by the Minister of Munitions on 31st March, 1916.

The Order of 6th November relating to the manufacture of copper wire and cable containing copper is cancelled.

All applications in reference to this Order should be addressed to the Ministry of Munitions of War, Priority Branch, 1, Caxton Street, Westminster, London, S.W.

B.—Restrictions on dealing in copper. 1. No person shall as from the date mentioned buy, sell or, except for the purpose of carrying out a contract in writing existing prior to such date, enter into any transaction or negotiation in relation to the sale or purchase of copper of any class whether wrought or unwrought situated outside the United Kingdom unless such person is authorised by a special permit from the Minister of Munitions to purchase or sell the same.

All applications for special permits should be made to the Director of Materials, Armament Buildings, Whitehall Place, London, S.W., and marked "Copper Permit" and all persons to whom such permits are granted should observe and perform all the conditions subject to which such permits may be granted.

2. All persons, except as mentioned below, shall send in to the Director of Materials, Armament Buildings, Whitehall Place, London, S.W., not later than 16th December, returns of:—

- (a) All unwrought copper held by them in stock or otherwise under their control at the above-mentioned date.
- (b) All unwrought copper due for future delivery to them at the above-mentioned date.
- (c) All contracts existing for the sale to or purchase by them of unwrought copper at the above-mentioned date.

Notwithstanding the above, no return is required from (1) any manufacturer or smelter of stock in hand or due for future delivery for the sole purpose of manufacture or smelting at his works, or (2) any person whose total stock in hand and due for future delivery does not exceed two tons.

Copper; Commandeering of —.

ACCORDING to an Order issued on January 2nd, the Minister of Munitions takes possession until further notice, upon specified terms, of all unwrought copper, including copper scrap and swarf, in any form whatsoever, subject to the following exceptions:

(A) Rough copper, copper ore, and copper scrap and swarf in the possession of, or due under an existing contract in writing for future delivery to, a smelter or refiner for the purpose of conversion into refined metal.

(B) All copper, including copper scrap and swarf, in the possession of or due under an existing contract in writing for future delivery to a manufacturer for use in such manufacturer's own works.

(C) Copper scrap and swarf specially excepted under the written authority of the Minister of Munitions.

If any person having control of any metal to which this notice applies, without the consent of the Minister of Munitions, sells, removes, or secretes it, or deals with it in any way contrary to any conditions imposed in any license or permit that may have been granted in respect thereof, he will be guilty of an offence against the Defence of the Realm (Consolidation) Regulations, 1914.

All existing licenses issued by or on behalf of the Minister of Munitions for dealing in any scrap or swarf to which this notice applies are cancelled.

The Minister of Munitions requires every smelter or refiner to make a return to the Director of Materials at the end of each calendar month, including the month of December, 1916, of the total quantities of refined copper of each description in stock, distinguishing between: (1) that sold for use on Class "A" or Class "B" work; (2) that allocated for such use in his own works; and (3) the residue not so sold or allocated; and he further requires every maker and holder of copper scrap or swarf to make a return to the Director of Materials at the end of each calendar month, including the month of December, 1916, of the total quantities of each class of such scrap or swarf in stock distinguishing between: (1) that sold for use on Class "A" or Class "B" work; (2) that allocated for such use in his own works; and (3) the residue not so sold or allocated.

All applications with regard to this order should

be addressed to the Director of Materials, A.M.2B., Armament-buildings, Whitehall Place, London, S.W., and marked "Copper Permit."

Copper concentrates; Possibilities in the wet treatment of —. L. Addicks. Met. and Chem. Eng., 1916, 15, 628—630.

CHALCOPYRITE and chalcocite concentrates are calcined and leached with dilute sulphuric acid which is recovered from the gases evolved during roasting. The percentage extraction of copper by leaching varies according to the degree of calcination; it may amount to over 90%, and the iron content may be lowered to 10%. The smaller the size of the particles, the more complete is the elimination of sulphur during the roasting and the higher the extraction of copper on leaching. A calcined product containing 15% copper, leached in a V-trough with a solution containing 5.6% of free sulphuric acid at a temperature of about 125° F. (52° C.), gave a residue at the end of the trough containing 8% copper. With efficient agitation during leaching, this was reduced to 3.5% Cu. The copper and silver still remaining can be dissolved by again roasting the residue in presence of salt, and leaching the chloridised product as before. The copper, silver, and gold in solution can be recovered by displacing with iron, by electrolysis, or by a combination of these methods.—J. N. P.

Zinc ores; Removal of iron from —. Min. and Eng. World, 1916, 45, 987.

THE presence of large percentages of iron in zinc concentrate has been a source of considerable trouble in certain districts. According to a method worked out in the University of Utah, the mixed zinc and iron sulphides are treated in a reducing atmosphere at 600° C., whereby the pyrites is converted into a form in which it will react with dilute sulphuric acid whilst the zinc sulphide remains unattacked. The requisite amount of cheap acid to ensure the success of the process will be obtainable by utilising the smelter gases.

Lead of radioactive origin; Atomic weight of —. T. W. Richards and C. Wadsworth. J. Amer. Chem. Soc., 1916, 38, 2613—2622.

FOUR samples of radio-lead from different sources had the following atomic weights:—From Colorado carnotite, 207.00; from Australian carnotite, 206.34; from Norwegian bröggerite, 206.12, and from Norwegian cleveite, 206.08. A specimen of ordinary lead had an atomic weight of 207.18. No new lines were observed in the ultra-violet or visible spectra of any of the specimens. The magnitude of the radioactivity of the leads did not bear any relation to the lowering of the atomic weight. (See also this J., 1916, 363, 1020.)

—W. P. S.

Tungsten ore exports from Malaya. Board of Trade J., Dec. 21, 1916.

THE total quantity of tungsten ores exported from the Federated Malay States in 1915 amounted to 291 tons, as compared with 261 tons in 1914 and 225 tons in 1913, most of this being ore containing less than 65% of tungstic acid. In addition to these exports, tungsten ores aggregating 407 tons were imported from other countries in 1915 and re-exported after treatment at separating works in the States. The value of wolfram alone exported from the Federated Malay States in 1915 was £32,174.

The quantities of wolfram imported into the Straits Settlements from the undermentioned territories during 1913—15 were as follows:—

	1913.	1914.	1915.
	Tons.	Tons.	Tons.
Burma	115	28	22
British Malay States	268	230	220
Siam	270	179	266
Netherlands East Indies	—	—	18

The value of the total exports of wolfram from the Straits Settlements in 1915 was £69,200, as against £51,130 in 1914 and £71,638 in 1913. The principal countries to which these exports were consigned are shown in the following table:—

	1913.	1914.	1915.
	Tons.	Tons.	Tons.
Belgium	21	—	—
France	129	103	183
Germany	327	307	—
United Kingdom	5	76	400

The excess of exports over imports is not due to the mining of wolfram in the Straits Settlements, but to its extraction from the tin ore sent for treatment to the large tin-smelting establishments in the Colony.

Scheelite production in New Zealand. Chem. Trade J., Dec. 30, 1916.

SCHEELITE is found in several sections of New Zealand in the neighbourhood of the gold mines both in the North and South Island, and has of late been quite extensively mined. The output has increased from 58 long tons, valued at £1200, in 1909, to 135 tons, valued at £13,000, in 1912, and to 194 tons, valued at £27,000, in 1915. Since September, 1915, the British Government have requisitioned all supplies of scheelite and other ore containing tungstic acid, and from that date all exports to other markets have been prohibited. It was reported in the latter part of 1915 that a large body of scheelite was located in the eastern part of the North Island in the Hawke's Bay district.

Tungsten and molybdenum ores in Tasmania. Bull. Imp. Inst., 1916, 14, 487—188.

ACCORDING to recent publications of the Geological Survey of Tasmania, promising deposits of molybdenite occur at Mount Stromach and Constable's Creek; deposits have also been observed near Lottah and at Upper Scamander, and in the Middlesex and Mount Claude districts. It is considered possible that the production of molybdenite may be profitable, though the amount in the ore is very small. There are important wolframite mines in the Middlesex and Mount Claude districts of Northern Tasmania; the total output is estimated at about 350 tons of concentrate containing 70% of tungstic acid. The present rate of output is about 6 tons of wolframite per month. Wolframite also occurs near Lottah, at Constable's Creek and Upper Scamander, and at Gipp's and Story's Creeks. Mining is at present confined to the last two localities, the output being about 12 tons of mixed tin and tungsten concentrates a month, of which about 7 tons consists of wolframite. It is estimated that the Story's Creek deposits can be worked to yield from 8 to 10 tons of wolframite per week.

Tungsten; Preparation of lamps of —. D. Kremer. Diss., Tech. Hochschule, Aachen. Engineering, 1916, 102, 623.

POWDERED tungsten was alloyed with manganese and the alloy heated in the electric arc to volatilise

the manganese. The product had a conchoidal fracture, and contained 97% W, 1.6% Mn, and small amounts of iron, silicon, and carbon. It was not possible to obtain lumps weighing more than 50 grms. by this method. When larger masses of metal were used, the arc heating period was so extended that the tungsten was oxidised. Tungsten will not dissolve in calcium, aluminium, or magnesium, nor will it alloy with copper or tin, but it forms both solid solutions and compounds with metals of the iron group and also with platinum.

Thermo-electricity and thermal conductivity of metals; A new effect, relative to the —. C. Benedicks. Comptes rend., 1916, 163, 751—753. (See also this J., 1916, 362.)

THE proportionality between the thermal and electrical conductivity of metals, as enunciated by Drude, is invalidated by the fact that a homogeneous metal when heated unequally generates electric currents which cause a considerable transport of heat. This is proved experimentally, and it is also shown that the thermal conductivity of metals is not independent, as hitherto supposed, of the dimensions of the sample. A bundle of thinly insulated copper wires was found to have a considerably lower thermal conductivity than massive metal of the same section, though the electrical conductivity remains the same.—J. N. P.

Results of co-operative work on determination of sulphur in pyrites. Moore. See VII.

PATENTS.

Furnace for fusion of metals and alloys; Recuperative crucible —. A. Hermansen, Ingelstad, Sweden. Eng. Pat. 15,887, Nov. 10, 1915. Under Int. Conv., Nov. 16, 1914.

A RECUPERATIVE crucible furnace, heated by gas from a producer beneath, has a vertical burner at the middle of the floor of the heating chamber. Air for combustion is preheated by the recuperator, and secondary air is delivered partly beneath and partly into the burner, while the products of combustion pass through channels in the outer wall of the furnace into a surrounding annular passage and thence to the recuperator. A chamber for collecting any waste metal falling through the burner is situated immediately below the latter, and means are provided for preventing the entry of such metal into the recuperator.—W. E. F. P.

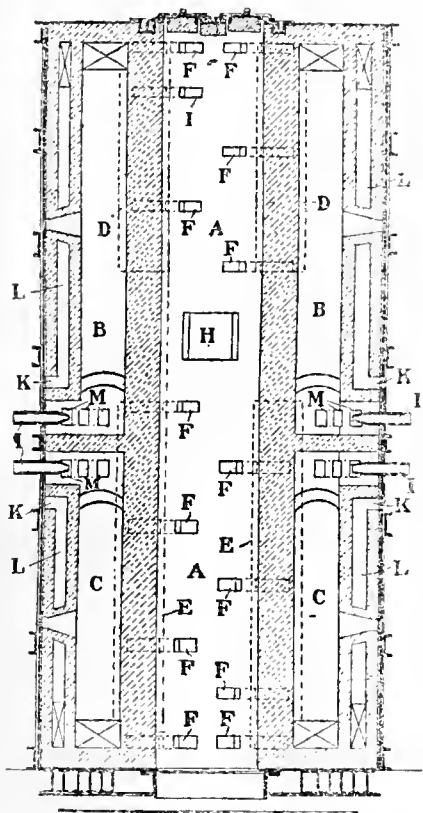

Furnace for melting metals [brass, gun-metal, etc.]. H. N. Davis and W. R. Twigg, Luton, Beds. Eng. Pat. 16,110, Nov. 15, 1915.

THE metal to be melted is charged through a fire-clay tube extending below the surface of the molten metal nearly to the bottom of the closed melting chamber or crucible, the latter having an external spout for discharge by overflow or being provided with other discharging means. (Reference is directed in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Act, 1907, to Eng. Pat. 15,165 of 1910; see U.S. Pat. 950,880; this J., 1910, 436.)—W. E. F. P.

Furnace for heating, hardening, tempering, annealing, carbonising, and other processes. A. Smallwood, London. Eng. Pats. 16,309, Nov. 19, 1915, 102,212, Nov. 19, 1915 (Appl. No. 12,200 of 1916), and 102,213, Nov. 19, 1915 (Appl. No. 12,201 of 1916).

THE furnace comprises an elongated vertical heating chamber, *a*, with combustion chambers,

b, c, in the walls, extending in opposite directions and heated by gaseous or liquid fuel supplied by the nozzles, *i*. The combustion chambers, *b, c*, communicate, at the top and bottom respectively, with flues, *d* and *e*, parallel to them, and these flues communicate with the chamber, *a*, by ports,

f, which may each be regulated by a movable bung. The air supply enters at *k*, and is heated by passing through flues, *l*, and thence through parallel return flues to the openings, *m*, close to the fuel nozzles, *i*. The heating chamber is closed at the bottom by a bung supported on a carriage which rests on rails. The rails are supported at their ends by links so that they may be lowered and the carriage and bung moved laterally. An annealing tank may be provided below the heating chamber, the intermediate space being completely enclosed. The mouth of the chamber is sealed by an annular sealing member carrying the bung, and the mouth of the tank is closed by a short, vertically movable tube carrying a similar annular sealing member.

—W. F. F.

Furnaces and the like; Gas fired melting — I. Hall, Birmingham. Eng. Pat. 102,174. Jan. 24, 1916. (Appl. No. 1072 of 1916.)

A FURNACE for melting metals is provided with atmospheric burners and pressure burners for alternative use. Both sets of burners are fed from a gas chamber of comparatively large capacity, and the pressure burners are also connected to a similar air distributing chamber. The burners are arranged in the furnace alternately, in the same horizontal plane, or they may be arranged in two series at different heights. —W. F. F.

Furnaces; Open-hearth regenerative — The Clyde Furnace Co. (A), Ltd., and W. Dixon, Glasgow. Eng. Pat. 102,234, July 22, 1916. (Appl. No. 10,341 of 1916.)

IN the repair of blocks of regenerative open-hearth

furnaces as described in Eng. Pat. 10,853 of 1913 (this J., 1913, 1116), the metal "centre" has an inclined slot at its inner end supporting a retaining plate which maintains the plastic repairing composition in position during its solidification. —W. F. F.

Furnaces heated by oil fuel for melting metals. J. Ward, A. P. Townsend, and R. G. Forgham, Birmingham. Eng. Pat. 102,278, Jan. 12, 1916. (Appl. No. 495 of 1916.)

An open-hearth metal melting furnace is mounted on two curved rockers which rest on two pairs of small rollers. The rockers carry toothed segments which engage with two spur wheels for tilting the furnace. A hydrocarbon burner is mounted at one end of the furnace so as to blow directly on the metal, and a waste gas outlet at the other end is connected to a flue passing under the furnace through which the air supply pipes pass to the burner. The oil supply pipe to the burner is heated by a jacket connected to a branch pipe from the main air supply pipe. (See also Eng. Pat. 22,789 of 1911; this J., 1916, 313.) —W. F. F.

Furnace; Crucible — H. Stokes, Birmingham. Eng. Pat. 102,092, Mar. 11, 1916. (Appl. No. 3672 of 1916.)

IN a crucible furnace the firebars are disposed across a rectangular, cast iron frame with relatively broad sides, and the brickwork is supported on a plate above and spaced apart from the frame. Air is supplied both above and below the grate from the ash-pit, and is also admitted above the frame through a front passage. When the furnaces are built in series, the spaces above all the grates communicate by means of a longitudinal air passage, and gaps are formed between the abutting ends of the frames. —W. E. F. P.

Zinc; Electro-deposition and extraction of — U. C. Tainton, London, and J. N. Pring, Chester. Eng. Pat. 16,336, Nov. 19, 1915.

ACCORDING to Eng. Pat. 7235 of 1911 (this J., 1912, 780) zinc was deposited in a lustrous, smooth, coherent form by the use of a high current density, which may amount to 600 amps. per sq. ft. of cathode, with an electrolyte having a high concentration of free acid, which may exceed 15%, and containing a small quantity of a suitable colloid. The present improvement relates to the winning of zinc from ores. For this purpose, where smoothness and lustre of the deposit are of little importance, it is found to be unnecessary in some cases to add a colloid to the electrolyte obtained by leaching the roasted ore. —J. N. P.

Copper; Precipitation of — A. Ramén, Helsingborg, Sweden. Eng. Pat. 100,588, May 18, 1916. Under Int. Conv., May 31, 1915. (Appl. No. 7119 of 1916.)

THE solution containing copper is placed in a closed container together with scrap metal such as iron or zinc. The container is then rotated or oscillated on a horizontal or sloping axis. When the precipitation of the copper is complete, steam or compressed air is admitted to the vessel and the contents are forced through a sieve which retains the scrap metal but allows the precipitated copper to pass through. The solution then passes to a filter-press or the like to separate the copper.

—J. N. P.

Copper; Process for treating — F. L. Antisell, Perth Amboy, N.J. U.S. Pats. (A) 1,204,925 and (B) 1,201,927, Nov. 14, 1916. Dates of appl., Feb. 16, 1911, and Nov. 1, 1912.

(A) PREHEATED copper is melted and then con-

ducted beneath a cover of boron trioxide or a non-metallic salt. (B) Copper melted under oxidising conditions is passed through or conducted beneath a layer of carbon or carbonaceous material.

—W. E. F. P.

Case-hardening compound. L. C. Mann, Stourport. Eng. Pat. 102,205, Mar. 24, 1916. (Appl. No. 4365 of 1916.)

A CASE-HARDENING compound is prepared by depositing barium carbonate on and in the pores of granules of charcoal. This precipitation can be brought about in the following ways:—(1) By treating the charcoal granules with a hot concentrated solution of baryta, and exposing to a stream of carbon dioxide; (2) by impregnating with barium carbonate held in solution by the action of carbon dioxide under pressure, and then expelling the excess carbon dioxide by removing the pressure and heating; (3) by treating with a soluble barium salt, such as the chloride, adding an alkali carbonate, and washing free from the alkali chloride; (4) by adding a hot solution of a soluble organic salt of barium which is converted into carbonate on heating.—J. N. P.

Welding: Process of — and composition therefor. J. A. Hope, Montreal, Canada. Eng. Pat. 102,237, July 26, 1916. (Appl. No. 10,548 of 1916.)

THE patent relates to the welding of a cutting edge of high-speed steel to a low-carbon shank in such a manner as to avoid the necessity of any separate process for rehardening the edge after the weld. The parts to be welded are heated to about 1500° F. (820° C.), and a welding mixture, consisting of ferro-silicon and burnt borax, together, in some cases, with ferro-manganese, is then applied to the prepared surfaces. The faces are brought together and submitted to a pressure of about 300 lb. for a few minutes. The joined parts are then raised to a temperature of from 2100° to 2500° F. (about 1150°–1370° C.), and removed to a press where they are subjected to a pressure of from 200 to 1000 lb., which is maintained until all "working" of the flux at the joint ceases. The high-speed steel edge is then immediately exposed to a cold air blast.—J. N. P.

Castling steel and other metals: Method and apparatus for —. R. and J. R. Hyde, Sheffield. Eng. Pat. 102,206, Mar. 24, 1916. (Appl. No. 4371 of 1916.)

Crucible furnaces: Lids or covers for —. J. and G. Keith, London. Eng. Pat. 102,365, June 22, 1916. (Appl. No. 13,060 of 1916.)

Electric welding: Method of —. D. H. Wilson, Franklin Township, N.J., U.S.A. Eng. Pat. 18,114, Dec. 29, 1915. Under Int. Conv., July 9, 1915.

XI.—ELECTRO-CHEMISTRY.

Overvoltage tables. III. Overvoltage and the periodic law. E. Newbery. Chem. Soc. Trans., 1916, 109, 1107–1117. (See this J., 1916, 1265.)

CATHODIC overvoltage appears to be one of the definite periodic properties of the elements. Based

on the consideration of a large number of determinations the following are regarded as overvoltages typical of their respective groups: Group 0, nil; I., 0.35 volt; II., 0.70 volt; III., 0.50 volt; IV., 0.15 volt; V., 0.42 volt; VI., 0.32 volt; VII., 0.25 volt; VIII., 0.18 volt. A rise of voltage of two equal steps is thus observed from groups 0 to II., followed by a gradual fall through the rest of the table. Of the metals examined the only ones not appearing in their proper groups are cobalt and palladium, values for the former as low as 0.18 volt not having been obtained, whilst the latter shows values above and below. When, under different conditions, such as varying current density, and in acid or alkali, metals have overvoltages corresponding with more than one group, in nearly all cases compounds of these metals are known in which the metals shows a valency corresponding with the characteristic valency of all the groups in which it is placed. The anodic overvoltages do not show the same degree of regularity as the cathodic, owing to the greater complexity of the anions involved, and to the formation of stable oxides and peroxides in many cases.—G. F. M.

Electrolytic manufacture of potassium chlorate. Betts. See VII.

Carbon tube furnace for testing the softening point and compressive strength of refractories. Griffiths. See VIII.

PATENTS.

Galvanic [dry] batteries. G. L., and G. J. A. Fuller, London. Eng. Pat. 102,291, Feb. 28, 1916. (Appl. No. 2968 of 1916.)

THE excitant, such as ammonium and zinc chloride, forming the electrolyte, is mixed with gum tragacanth, tapioca, or the like, and the mixture baked in an oven to remove moisture and render the particles crisp. The dry material is packed in the usual manner in a zinc case around a carbon rod and manganese dioxide depolariser, and water added when the cell is to be used.—B. N.

Gaseous bodies; [Electrical] method and means for recovering certain constituents from —. W. A. Schmidt, Los Angeles, Cal., and L. Bradley, East Orange, N.J., Assignors to Research Corporation, New York. U.S. Pat. 1,201,906, Nov. 14, 1916. Date of appl., July 23, 1911.

A GASEOUS mixture containing suspended dust particles and constituents having different condensing temperatures, is subjected to an electrical discharge in an electric field to precipitate the dust, and then cooled by admixture of a cooler gas. The temperature is reduced to a point producing condensation of one constituent in the form of a cloud, and an electrical discharge is passed to precipitate this constituent. The process is repeated at lower and definite temperatures to form clouds of definite composition, and these are each treated in turn electrically, until the material having the lowest condensing temperature has been finally separated.—B. N.

Discharge of electricity into gases; Means for producing —. W. A. Schmidt, Assignor to International Precipitation Co., Los Angeles, Cal. U.S. Pat. 1,201,907, Nov. 14, 1916. Date of appl., June 17, 1915.

THE collecting electrode, in the electrical precipitation of suspended particles from gases, is made in the form of a pipe, through which the gas to be

treated is passed. The discharge electrode is formed of several smooth elongated conductor members, extending longitudinally through the pipe, connected together electrically but spaced apart to form a polygon, the intensity of the electric field adjacent to each conductor member being thus controlled by the influence of adjacent conducting members.—B. N.

Electrolytic battery. McKay Copper Process Co., Assignees of H. S. McKay, Norwich, Conn., U.S.A. Eng. Pat. 100,264, Jan. 26, 1916. Under Int. Conv., Apr. 9, 1915. (Appl. No. 1278 of 1916.)

XII.—FATS; OILS; WAXES.

Esters of oleic acid and their hydrogenated products. C. Ellis and L. Rabinovitz. J. Ind. Eng. Chem., 1916, 8, 1105—1108.

THE methyl, ethyl, propyl, isobutyl, amyl, benzyl, and glyceryl esters of oleic acid were prepared. They were all liquid at the ordinary temperature, and yielded practically saturated products when hydrogenated in the liquid state, at an increased temperature, in presence of reduced nickel. Some of the characters of the esters and of their hydrogenation products are shown in the following table:—

Ester.	Acid value.	Iodine value.	Hydrogenation product.	
			M.pt., °C.	Iodine value.
Methyl oleate	1.3	87.0	37	0.4
Ethyl oleate	0.6	83.3	31	5.3
Propyl oleate	0.5	77.9	27	1.3
Isobutyl oleate	0.4	75.7	25	0.2
Amyl oleate	0.7	71.3	22	1.7
Benzyl oleate	0.7	62.3	28	6.3
Glyceryl mono-oleate	0.6	69.4	59	6.5

A product obtained by heating together equivalent proportions of aniline and oleic acid under a reflux condenser, had an acid value of 3.6, iodine value 69.5, and m.pt. 34° C. When hydrogenated it yielded a product of m.pt. 76° C. and iodine value 30.5.—A. S.

Hides and other animal by-products; Disinfection of — for importation into the United States.

JOINT Regulations have been drawn up by the Secretary of Agriculture and the Secretary of the Treasury of the United States, governing the certification and disinfection of hides, fleshings, hide cuttings, etc., for entry into the United States. The circular of the Treasury Department (T.D. 36, 754) containing these regulations, which took effect on Jan. 1st, 1917, is reprinted in the "Board of Trade Journal" of Dec. 21st, 1916, pp. 884—887.

Sumach; Indian —. Puran Singh, Indian Forest Bulletin No. 31, 1916.

SPECIMENS of the bark of Indian sumach (*Rhus*

colinus) from various localities, dried in the shade, contained from 8.25 to 20.86% of tannin. That giving the highest yield was collected in the rainy season, but on the whole the results appear to throw little light on the question of the best time for collection. In the case of the leaves, however, it seems clear that they should be collected in India in the autumn, after the rains, since specimens collected during this time contained from 18 to 22% (in one case 31%) of tannin, as against 6 to 13% in leaves collected during spring and summer. In winter the percentage falls. The leaves gathered in autumn thus compare favourably as regards tannin content with European sumach, which averages 18–20% tannin.

XVI.—SOILS; FERTILISERS.

Soils; Use of two indirect methods for the determination of the hygroscopic coefficients of — F. J. Alway and V. L. Clark. J. Agric. Res., 1916, 7, 345–359.

THE hygroscopic coefficient of a soil, *i.e.*, the maximum water content after exposing it in an air-dried state to a saturated atmosphere until equilibrium has been established, can be deduced from its maximum water capacity, but the values obtained are frequently so different from those which result from direct determinations that the method cannot be recommended. Quite satisfactory results are, however, obtained by calculating the coefficient from the amount of hygroscopic moisture found in a soil which has been brought into equilibrium with an atmosphere only partially saturated. If *a*, *b*, be the hygroscopic coefficients of two soils A and B, of which A is a typical soil whose coefficient has been determined directly; and if *a'*, *b'*, be the amounts of hygroscopic water found in them after being brought into equilibrium with a partially saturated atmosphere (and these values are determined directly much more readily than *a* and *b*): then $a : a' = b : b'$.—E. H. T.

Carbon in soil; Determination of total — by wet combustion. C. J. Schollenberger. J. Ind. Eng. Chem., 1916, 8, 1126–1127.

THE author has obtained good results in the determination of total carbon in soils by a modification of the wet combustion method of Ames and Gaither (this J., 1914, 800). A mixture of phosphoric acid and sulphuric acid with chromic anhydride is used as oxidising agent, and barium hydroxide is used to absorb the carbon dioxide in a Meyer absorption apparatus or a Truog head tower (J. Ind. Eng. Chem., 1915, 1015).—A. S.

Nitrogen-fixing bacteria; New (Russian) studies of — V. L. Omelianskij and M. Solunskov. Arch. des Sciences biol. L'Institut. impér. de médec. experim. à Petrograd, 1915, 18, 459–482, 338–377, 327–337; 19, 162–208. Bull. Agric. Intell., 1916, 7, 941–945.

THE nitrogen-fixing organisms, *Clostridium Pasteurianum* and *Azotobacter chroococcum*, were found to be very prevalent in Russian soils, and the power of the former was slightly greater than that of the latter. The organisms which act in combination with the nitrogen-fixing bacteria of upper soil strata are very numerous and play a most important rôle in soil activity; and the synergetic activity of both kinds varies with the species and the environment. In some cases the species which were added to the cultures of nitrogen-fixing bacteria supplied the carbon compounds necessary for the latter to fulfil their specific function: aerobic organisms, such as *Azotobacter chroococcum* favour the activity of anaerobes, *e.g.*, *Clostridium*, by creating an oxygen-free atmosphere; and the injurious, acid disassimilation products of *Clostridium* are neutralised by the alkaline product of the azotobacter. The optimum form of micro-organic combination is that of symbiosis between aerobic and anaerobe, and especially between the species mentioned. To investigate the interdependence of nitrogen fixation and the consumption of non-nitrogenous organic substances, *Azotobacter* and *Clostridium*, isolated from different soils, were cultivated in a medium containing in 100 c.c.: 80 c.c. drinking water, 20 c.c. linseed extract (5%), 2 grms. dextrose, 0.1 gm. potassium phosphate, 0.05 gm. magnesium sulphate, and 0.5 gm. calcium carbonate. The experiments lasted six weeks, and at intervals of five days, sugar and nitrogen determinations were performed. The curves obtained, representing nitrogen fixed and sugar consumed, ran parallel, and showed unmistakably that a close relation existed between the assimilation and the disassimilation processes in the cell: they showed continuous increases until the sugar was used up, the maximum rise taking place between the fifth and the fifteenth day. Although the absolute amount of nitrogen fixed in the first five days was very small, it was relatively much greater than the quantity of sugar consumed. The efficiency diminished after this period, and during the last five days it remained stationary.—E. H. T.

Phosphorus pentoxide [in fertilisers]; Determination of — after citrate digestion. O. C. Smith. J. Ind. Eng. Chem., 1916, 8, 1127–1128.

BY the following method it is possible to obtain in less than one hour a clear solution from the filter paper and residue remaining after digesting with neutral ammonium citrate solution, and filtering, in the analysis of fertilisers. The paper and residue (from a 2-grm. sample) are digested with 10 c.c. of concentrated sulphuric acid and 50 c.c. of nitric acid (1:1) until white fumes appear, when 1–2 c.c. of concentrated nitric acid is added to the boiling solution and digestion continued until

white fumes again appear. These operations are repeated until the solution is colourless, after which the usual procedure is followed.—A. S.

Plants; Mechanism of absorption of salts in —. E. Pantanelli. *Rend. Accad. Sc. Fis. Mat. Napoli*, 1915 [iii], 21, 55—63. *J. Chem. Soc.*, 1916, 110, i., 871—873.

THE author has made extensive series of experiments on the absorption of many different salts from their solutions by fresh-water plants, terrestrial plants, yeast, and marine algae. The last two classes of organisms were totally immersed in the solutions, whilst only the roots of the land plants were immersed, after the plants had been reared in nutrient solutions. The principal results obtained are briefly as follows. In general, the absorption of one ion of a salt is quite independent of the absorption of the other. In a few cases, the two ions of a salt are absorbed proportionally, the absorption being apparently one of undissociated molecules, but in all such cases, either the salt contains a toxic ion which alters or tends to alter the osmotic properties of the plasma, as is shown by the subsequent behaviour of the same cells towards plasmolytic agents, and towards the penetration of dyes, etc., or both ions have nutrient properties, or both have toxic or unfavourable properties. That the proportional absorption of the ions is accidental is shown by the fact that the same ions in the same salts are absorbed by some plants in equivalent proportions, whereas by other plants, or even by the same plants under different external or internal conditions, they are absorbed in proportions quite different from those corresponding with undissociated molecules. In some cases the cation and in others the anion is absorbed the more, in accordance with the preference which each species of plant exhibits. Comparison is drawn between the results obtained with two salts having one common ion, whilst the other ion is harmful in one case and, although similar, nutrient or useful in the other, for instance, with barium and calcium chlorides, lithium and potassium nitrates, ammonium and potassium sulphates, zinc and magnesium sulphates, potassium arsenate and phosphate. In most cases there is complete independence in the absorption of the two ions, the useful cation penetrating with the same rapidity in presence of a nutrient anion as if accompanied by a poisonous anion; the latter, however, remains outside, whereas the nutrient anion enters the plant in large amount. Similar relations govern the behaviour of a useful anion towards nutrient and harmful cations. In a few instances, the absorption of a nutrient cation was found to be restricted by the presence of a harmful anion, and *vice versa*. No case has been observed in which the absorption of a toxic ion is facilitated by an accompanying nutrient ion. During the initial stages of the growth of plants in these salt solutions, increase of acidity or alkalinity of the external solution occurs in consequence of the predominating absorption of one of the two ions. After some hours, or sometimes days, the cell exhibits the power to develop in the liquid a more favourable degree of acidity, this being attained by the excretion of other ions; this effect is most marked with the marine algae. Whilst those ions which readily enter the cells do so with such rapidity that the concentration inside may exceed that outside after a few moments, those showing the opposite behaviour do not, as a rule, reach a state of equilibrium except in those cases where they are supplied in toxic concentration and alter completely the osmotic properties of the plasma. Further, the absorption of ions of the first type is not continuous, but resembles the damped vibration of a pendulum, a large and vigorous absorption being followed by a partial excretion

of the same ion and then by a second smaller absorption and an excretion, and so on, these processes being repeated until a definite proportion is established between the internal and external concentrations of the particular ions. The curves connecting the proportion of ion absorbed under similar conditions with the concentration are typical adsorption isotherms for all ions, although the curves for the two ions of a salt do not coincide and vary with the specific organism and with other factors. As regards the mechanism of these processes the conclusion is drawn that the absorption of salts insoluble in the lipoids is possible only in so far as these salts are dissociated. The absorption is facilitated by the presence of H^+ or OH^- ions in the external solution or in the plasma. Confirmation is obtained of the independence of the absorption of water from that of the ions present in it, cellular colloids thus exhibiting the property of negative adsorption.

Nitrites and ammonia; Presence of — in diseased plants; its significance with regard to crop rotation and soil depletion. P. A. Bonquet. *J. Amer. Chem. Soc.*, 1916, 38, 2572—2576.

THE presence of nitrites in plant tissues, in the cases observed, comprising the sugar beet, tobacco leaves, potato leaves and tubers amongst others, is due to the reducing power of internal bacteria, and this reduction, which may proceed as far as ammonia, is the cause of the nitrogen starvation of plants affected by certain peculiar diseases. Starvation may occur even when the soil is rich in nitrates, and these nitrate-reducing bacteria may be a direct factor in soil depletion where crop rotation is not practised, owing to the increased virulence and invading power of the micro-organisms. A lack of crop rotation provides soil organisms a better opportunity to establish themselves in the veins and tissues of plants by means of adaptation.—G. F. M.

Seeds; Treatment of — [before sowing]. C. E. De Wolf, London, and H. E. Fry, Dorchester. Eng. Pat. 102,081, Feb. 14, 1916. (Appl. No. 2172 of 1916.)

THE productivity of seeds may be increased by steeping them, before they are sown, in natural mineral waters such as are used for medicinal purposes. Cereals are treated for 24 hours, or for a shorter period if an electric current be passed through the liquid (0.75 amp. per 10 gallons). The steeping is carried out in wooden or earthenware tanks; the seeds, which should not exceed 18 in. in depth, must be well immersed and the liquid occasionally stirred. The treated seeds are either dried at about 90° F. (32° C.), or spread on a floor, sprinkled with petroleum at the rate of $\frac{1}{2}$ -pint per bushel, and turned over three or four times; they should then be sown as soon as possible.—E. H. T.

PATENT.

Sugar; Method of recovering— from massecuite. H. A. Vallez, Bay City, Mich. U.S. Pat. 1,204,617, Nov. 14, 1916. Date of appl., Jan. 11, 1916.

MASSECUTE is placed in a receptacle containing a screen on which a uniform layer of sugar crystals is deposited by applying air pressure to one side of the screen and alternately immersing the screen in, and withdrawing it from, the massecuite. The layer of crystals is afterwards washed with steam under pressure and then dissolved by introducing a solvent into the receptacle and agitating the screen. The screens may be in the form of disc-shaped chambers with perforated walls mounted on a rotating hollow shaft inside a horizontal cylinder.—J. H. L.

XVIII.—FERMENTATION INDUSTRIES.

Alcohol; An accurate aeration method for the determination of— in fermentation mixtures. A. W. Dox and A. R. Lamb. J. Amer. Chem. Soc., 1916, 38, 2561—2568.

THE isolation of alcohol from fermentation mixtures in a concentration suitable for oxidation to acetic acid cannot be carried out quantitatively by distillation methods even from a saturated salt solution. Results accurate to within 1.5% were, however, obtained by aspirating air at the ordinary temperature through the dilute alcoholic liquid saturated with ammonium sulphate, and absorbing the alcohol in concentrated sulphuric acid. The aeration train consists of a guard tube containing oxidising solution, the alcoholic solution containing ammonium sulphate in a gas washing bottle, and two tubes containing the sulphuric acid. Air is drawn through at the rate of about 25 litres an hour, for 8—10 hours, when practically all the alcohol will have been absorbed by the sulphuric acid. The alcohol-sulphuric acid solution is then mixed with 10—15 grms. of bichromate in aqueous solution and after standing 15 minutes the acetic acid is distilled off, care being taken that the volume of liquid does not get too small, and distillation being continued until all the volatile acid has passed over. The distillate is titrated with standard baryta solution. Volatile fatty acids in the fermentation mixture are not volatilised under the conditions described above. Acetone, though volatilised, is but slightly oxidised; methyl alcohol is almost completely oxidised to carbon dioxide and water, but esters such as ethyl acetate interfere with the determination and must be estimated separately.—G. F. M.

β -Glucosidase; Influence of acetic acid on the synthetic and hydrolytic action of—. E. Bourquelot and A. Aubry. J. Pharm. Chim., 1916, 14, 359—363. (See this J., 1915, 728.)

THE catalytic effect, at the ordinary temperature, of β -glucosidase (contained in emulsin) on the synthesis of β -methyl-*D*-glucoside in aqueous methyl alcohol, is almost unaffected by the presence of acetic acid in quantities below 0.10 gm. per 100 c.c. The synthetic action decreases, however, with further increase in the acetic acid and reaches zero in presence of 2 grms. of acid per 100 c.c. The hydrolytic action of the enzyme,

under similar conditions, is also diminished when the acetic acid exceeds 0.10 gm. per 100 c.c. This diminution in activity is shown to be due to an actual destruction of the enzyme. α -Glucosidase, the similar enzyme present in bottom fermentation beer yeast, is much more sensitive.—F. C.

PATENTS.

Enzyme-fillers. M. Kiutsi, Hakodate, Japan. Eng. Pat. 16,096, Nov. 15, 1915. Under Int. Conv., Nov. 15, 1914.

A SECTION of the stem of bamboo or other plant of the *Graminaceæ*, open at the top and closed by a node at the bottom, is converted into a cylindrical dialysing vessel, by removing the outer layers of the stem, leaving the thin inner membrane intact, and then repeatedly extracting with boiling water. It is claimed that if such a vessel, filled with urine, serum, or other liquid containing enzymes, is immersed in water, the enzymes alone will pass through the membrane.—J. H. L.

Wine; Process for ageing—. A. Lachman. Berkeley, Cal. U.S. Pat. 1,204,669, Nov. 14, 1916. Date of appl., July 28, 1913.

A CONTINUOUS current of wine, flowing under pressure, enters a large vessel whereby its velocity is greatly reduced. In the vessel it is heated and subjected to an electric current, and on leaving it communicates its heat, in a counter current apparatus, to fresh wine flowing towards the vessel.—J. H. L.

Beverages; Process of manufacturing unfermented—. H. Heuser, Chicago, Ill. U.S. Pat. 1,204,869, Nov. 14, 1916. Date of appl., June 12, 1916.

A THICK mash of grain containing proteins, is subjected to proteolysis by means of lactic bacteria between 20° and 40° C. The bacteria may subsequently be destroyed by addition of hot water, and after the acidity has been reduced, the liquid may be separated from the solid matter and hopped.—J. H. L.

Enzyme fillers. M. Kiutsi. Fr. Pat. 480,236, Nov. 15, 1916.

SEE Eng. Pat. 16,096 of 1915; preceding.

XIXA.—FOODS.

Food colouring substances; Use of the spectrophotometer for the examination of—. W. F. Mathewson. J. Assoc. Off. Agric. Chem., 1916, 2, 164—169.

BY means of a Koenig-Martens spectrophotometer fitted with a Rutherford prism the author has determined the absorption by dye solutions of light of various wave lengths. The results are calculated into "extinction coefficients," e , using the formula: $e = \log \tan a_1 + \log \cotan a_2$, where a_1 and a_2 represent the angular readings with the Schütz glass cube before the right and left parts of the slit, respectively. The results for seven permitted dyes (Naphthol Yellow S, Orange I, Ponceau 3R, Erythrosine, Amaranth, Indigo-Carmine, and Light Green SF Yellowish) are given in tabular form, the figures corresponding with the values for 0.001% solutions. The determination of a dye is made by determining the approximate concentration of its solution by the use of this table, changing the concentration, if necessary, so that the values for e will be from 0.6 to 1.00 in the

region of maximum absorption, making a standard solution of the same calculated concentration from a pure colour, and determining the absorption constants for each under the same conditions. The method is applicable to dyes other than those mentioned, to natural colouring substances, and to mixtures of dyes.—W. P. S.

Coal-tar dyes; Modification of Price's method for the separation of the seven permitted—to include Tartrazine. C. Estes. J. Ind. Eng. Chem., 1916, 8, 1123—1124.

ACCORDING to Food Inspection Decision 164, Tartrazine may be used in the United States to colour food products, in addition to the seven colours previously permitted. Price's scheme for the separation and detection of the permitted colours (this J., 1912, 41) has therefore been modified so as to include Tartrazine. The dyes are first isolated by dyeing on to wool from a slightly acid aqueous solution, and then removed from the wool by boiling with a very dilute solution of ammonia. A small quantity of the separated dyes is triturated with 25 c.c. of a supersaturated solution of ammonium sulphate, filtered, and the residue washed with small portions of the ammonium sulphate solution. The residue is examined as described by Price (*loc. cit.*). The solution may contain Amaranth, Tartrazine, and a small quantity of Naphthol Yellow S. The Naphthol Yellow is removed by shaking several times with ethyl acetate until the latter is no longer coloured yellow, and Amaranth and Tartrazine are extracted from the residual aqueous solution by means of acetone. The acetone solution is diluted with water, evaporated to expel the acetone, then supersaturated with sodium chloride, filtered, and the filter and residue washed with a supersaturated solution of sodium chloride until the washings are no longer coloured yellow. Tartrazine is separated in a pure state from the sodium chloride solution by adding excess of glacial acetic acid or concentrated hydrochloric acid and extracting with acetone, and Amaranth is separated in a similar manner from the residue on the filter.—A. S.

Crude fibre; Determination of—. C. E. Mangels and P. F. Trowbridge. J. Assoc. Off. Agric. Chem., 1916, 2, 132—134.

THE following method was found to be rapid and to yield satisfactory results. The fat-free substance was mixed with 200 c.c. of 1.25% sulphuric acid, heated to boiling, and boiled for exactly 30 mins.; the mixture was then filtered through muslin (98 by 102 threads per sq. in.), the insoluble portion washed with hot water, and then boiled for 30 mins. with 200 c.c. of 1.25% sodium hydroxide solution. The alkaline solution was filtered through the same muslin filter, and, after washing, the residue was rinsed into a Gooch crucible, washed with alcohol, dried at 102° C., and weighed. The contents of the crucible were then ignited and re-weighed, the difference between the two weights giving the amount of crude fibre present. The results obtained were slightly higher than those found by the official (American) method, *e.g.*, 11.08% against 10.12%. Still higher results were obtained when the filtration after the acid digestion was omitted.—W. P. S.

Agar agar; Analysis, purification, and some chemical properties of—. C. R. Fellers. J. Ind. Eng. Chem., 1916, 8, 1128—1133.

ANALYSIS of fifteen samples of agar from widely different sources gave the following results:—moisture, 14.57—17.84 (average 16.57); protein (N x 6.25), 1.53—3.26 (2.34), nitrogen-free extract, 72.72—78.21 (76.15); ether extract, 0.17—0.45

(0.30); crude fibre, 0.39—1.50 (0.80); ash, 3.08—5.68 (3.85); and silica, 0.31—1.11 (average 0.68) per cent. A specially purified commercial agar for bacteriological purposes contained: moisture, 5.72; protein, 1.14; nitrogen-free extract, 89.25; ether extract, 0.32; crude fibre, 0.15; ash, 3.12; silica, 0.29 per cent. High ash or silica content is indicative of an inferior product. An aqueous solution of agar is acid to phenolphthalein. A purified agar for use in bacteriological work where a gelatinising agent containing a minimum of nutrients is desired, may be prepared by washing agar shreds in a dilute solution of acetic acid, washing out the acid, dissolving the agar to a 5% solution, and pouring the hot solution slowly into a large volume of 95% alcohol or acetone. The precipitated agar contains considerably less nitrogen than the original material. Part at least of the nitrogen compounds present in agar is available as nutriment for micro-organisms. The setting power of aqueous solutions of agar is not destroyed by acid or alkali between the limiting concentrations of 4.5% HCl and 5% NaOH; but if the solution be heated for 15 mins. under a pressure of 1 atmosphere the range of concentrations within which solidification occurs is reduced to from 2% HCl to 4.5% NaOH. The gelatinising power is increased by addition of peptone and slightly diminished by potassium chloride.—A. S.

Quantitative microscopy. Wallis. See XXIII.

PATENTS.

Sterilising and preserving alimentary products; Method of— and means therefor. C. Jovignot. Paris. Eng. Pat. 1275, Jan. 16, 1914. Under Int. Conv., Jan. 18, 1913.

THE receptacle containing the food is closed with a double lid, the lower lid being a thin metal sheet, a portion of which is perforated with small holes, and the outer lid being of stouter metal with one or more perforations. Between the two lids is a layer of cotton or other filter material. In another form of construction a single lid is used, perforated with one hole, through which passes a short tube with a thin plate or disc attached to its inner end. The space between the plate and lid is packed with the filtering material. The side of the tube is perforated so as to allow an air passage from the exterior through the filter to the interior. Sterilisation is effected in a steam or air steriliser, and when completed the receptacles are allowed to cool in presence of air or an inert gas. When cold, the openings in the outer lid are closed with solder.—J. H. J.

Cereal preparations. W. A. Rullman, Red Bank, N.J., U.S.A. Eng. Pat. 16,531, Nov. 23, 1915.

BARLEY and wheat grains are steeped separately for two days, then placed in heaps about 14 in. high and allowed to stand for germination to take place. The heaps are aerated and moistened at intervals. After germination the rootlets are removed, the wheat is ground to a pulp, and to it is added half its weight of the malted barley in the form of extract. The mixture is heated at 100° F. (38° C.) for an hour, at 153° F. (67° C.) for 15 mins., and at 156° F. (69° C.) for 15 mins. with stirring, when part of the starch is converted into maltose and dextrin. It is now heated at 165° F. (74° C.) for 15 mins., 20% of agar-agar added, and the heating continued for half an hour. After cooling, salt and yeast are added, the mass allowed to stand for 12 hours, and baked. It is then reduced to a granular form, and consists of 75% of nitrogenous matter, starch, maltose, and dextrin, and 25% of bran and agar-agar.—J. H. J.

XIXB.—WATER PURIFICATION; SANITATION.

Sewage; Recovery of fats and nitrogen compounds from —. S. Rideal. Assoc. of Managers of Sewage Disposal Works. Chem. Trade J., 1916, 59, 571–572.

PRESSED dry sewage sludge may contain as much as 8% of fat which can be extracted by means of a solvent; the lowest figure is 3.5% and the average for peace-time sludge is probably 5%. Assuming that the percentages of fat in sewage from military camps and from towns are the same, it is estimated that the camps in this country would yield 100 cwt. of fats daily, and the rest of the population 4000 cwt.; probably not more than 20% of this is saponifiable, so that the daily yield of glycerin, with 10% recovery, would amount to 8 cwt. and 80 cwt. respectively. Before the war, from 12 to 15 tons of fat per day was recovered at Bradford, and was valued at £8 to £10 per ton. In Dresden it was the practice to separate the sludge mechanically; after partial drying it contained 13.35% of fat which was extracted by ethylene trichloride.

The production of gas from sludge was studied in Paris by Cavel in 1912; the sludge was burnt with 20% of coke in a producer, giving a gas of 3500 cal. per cub. m. It was estimated that from Paris and the Seine Departments 300 tons of dry sludge could be obtained daily, yielding 24,500 cub. m. of gas worth 147,000 fr. per annum. These gases might be used in the Heusler engine, in which the nitrogen compounds are recovered.

If all the nitrogen in sewage could be recovered, it is estimated that our military camps would yield 11,640 tons per annum and the civil population 116,400 tons. It is suggested that the free ammonia should be recovered from sewage by heating, possibly after addition of lime; heat exchangers are now designed to work with a very small loss of energy, so that the removal of the free ammonia from a tank effluent is not impossible. Another method suggested to recover the free ammonia is by means of air. In the ordinary process of aeration and activation, the escaping gases do not contain ammonia, but when air is passed through ordinary sewage, the ammonia is removed. If the "activation" is carried out in presence of lime, nitrification will probably not be complete and some ammonia will be present in the escaping gases. Dried activated sludge, with 10% moisture, contains 5 to 9% of nitrogen, and if retorted, should give higher yields of ammoniacal liquor than are obtained from coal in gas works.

To recover nitrates from effluents after oxidation of ammonia, it is suggested that a filter bed with no effluent drain, protected from rainfall, might be irrigated with the effluent, so that the nitrates would become gradually concentrated by evaporation.

Fume poisoning from nitric and mixed acids. L. A. De Bois. National Safety Council. Chem. Section. Detroit, Oct., 1916. J. Ind. Eng. Chem., 1916, 8, 1162–1163.

THE best means of preventing poisoning by nitrous

fumes in works where nitric acid and mixed acid are used, is the provision of efficient ventilation. In the E. I. du Pont de Nemours Powder Co.'s works, the fumes are removed by means of large down-draught exhaust fans. The earthenware pots in which cotton is nitrated are placed in partial enclosures over slatted openings through which the fumes can be drawn at a velocity of about 830 ft. per minute between the slats with full opening, and in some cases 2500 ft. per minute close to the top of the pot. Before an efficient exhaust system was developed, good results were obtained by spraying ammonia or ammonium carbonate solution directly into the air by compressed air atomisers. Each atomiser consumed about 2½ cub. in. of ammonia solution of 30° B. (sp. gr. 0.875) per hour at an air pressure of 25 lb., and this was sufficient to neutralise "rather dense" fumes over an area of about 252 sq. ft. of floor surface. Respirators are not generally very satisfactory. The most efficient type was an aluminium respirator having an exhaust valve and inflated rubber face-cushion, and with the usual sponge replaced by a disc of "Filtros," 2½ in. diam. by 1½ in. thick, fitted with rubber gaskets and moistened with a 20% solution of caustic potash. The discs may be washed and recharged until the pores are blocked, when they can be replaced at a cost of about 25 cents (1s. 0½d.). —A. S.

Formaldehyde and potassium permanganate fumigant. J. R. Hill. Pharm. J., 1916, 97, 589–590.

THE usual method of using the fumigant is to add 8 oz. of permanganate crystals to 10 fl. oz. of commercial formalin, a mixture which is sufficient to fumigate a room containing 500 cb. ft. of air. The heat of reaction is sufficient to vaporise a large part of the formalin, but a considerable proportion of the formaldehyde is wasted owing to conversion into formic acid. The nature of the reaction is indicated by the following equations:—(1) $3\text{HCOH} + 2\text{KMnO}_4 = 3\text{HCOOH} + \text{K}_2\text{O} + 2\text{MnO}_2$, (2) $\text{K}_2\text{O} + 2\text{HCOOH} = 2\text{HCOOK} + \text{H}_2\text{O}$, (3) $3\text{HCOOH} + 2\text{KMnO}_4 = \text{K}_2\text{CO}_3 + 2\text{MnO}_2 + 3\text{H}_2\text{O} + 2\text{CO}_2$. The presence of formate in the liquid at the end of the reaction was proved by the reduction of mercuric chloride solution to metallic mercury, and by the formation of ferrie formate. Fumigation by formaldehyde can be effected without danger by direct boiling of formalin in an open vessel. Fumigation may be replaced with advantage by direct spraying of a 1% solution of formaldehyde on the walls.—J. H. J.

Lead arsenate; Boiling method for the determination of water-soluble arsenic in —. G. P. Gray and A. W. Christie. J. Ind. Eng. Chem., 1916, 8, 1109–1113.

THE soluble arsenic compounds in commercial lead arsenate preparations can be completely extracted by boiling with water for 5–10 mins., whereas complete extraction is almost impossible by digesting with cold or tepid water as in the provisional methods recognised by the Association of Official Agricultural Chemists (U.S.A.). No solution or hydrolysis of lead arsenate occurs even on prolonged boiling with water or by digesting on the steam bath for several hours. The following rapid method is recommended both for ordinary analytical work and for factory control. It gives higher results than the provisional methods referred to, but is considered to be more accurate than the latter. 0.5 gm. of the dry powdered sample is boiled briskly for 10 mins. with 200 c.c. of water. If the liquid is cloudy or the sample does not settle readily, the mixture is digested on the steam bath for 1 or 2 hours or until the supernatant liquid is clear. The solution is filtered, the filter

washed with a small quantity of hot water, and the filtrate treated with 1 gm. of potassium iodide and 4 c.c. of concentrated sulphuric acid, evaporated till the volume is reduced to about 40 c.c., diluted to 200 c.c., and any free iodine removed by means of $N/20$ thiosulphate. After adding methyl orange and nearly neutralising with concentrated sodium hydroxide solution, an excess of sodium bicarbonate is added, and the arsenic titrated with $N/20$ iodine solution, using starch paste as indicator. The aqueous extract may be tested for lead and the latter, if present, removed in the usual way before titrating the arsenic, but in most cases an appreciable amount of lead is not present.—A. S.

Paris green analysis: An oxalate-iodide process for —. C. A. Peters and L. E. Fielding. J. Ind. Eng. Chem., 1916, 8, 1114—1115.

ABOUT 0.25 gm. of the sample is treated with less than 1 c.c. of sulphuric acid (1:10), diluted to 50 c.c., boiled for 2 mins., and 2 grms. of oxalic acid crystals added slowly to the hot liquid. After again heating to the boiling point, the mixture is allowed to stand overnight, the precipitated copper oxalate collected on an asbestos filter, washed, treated with water and 5—10 c.c. of sulphuric acid (1:1), heated nearly to boiling, and titrated with permanganate. The filtrate is treated with an excess of dry sodium bicarbonate, and the arsenic determined by titration with iodine.—A. S.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Opium and cocaine: Prohibited importation of —.

A ROYAL Proclamation dated December 11, 1916, prohibits the importation of cocaine and opium excepting under licence. The word "cocaine" includes all preparations, salts, derivatives, or admixtures prepared therefrom or therewith and containing 0.1% or more of the drug, or any solid or liquid extract of the coca leaf containing 0.1% or more of the drug. The word "opium" means raw opium, powdered or granulated opium, or opium prepared for smoking, and includes any solid or semi-solid mixture containing opium.

New Defence of the Realm Regulations have been made to carry out the provisions of this Proclamation.

Morphine: Microchemical distinction of — from codeine. O. Tummann. Apoth.-Zeit., 1916, 31, 148—150. J. Chem. Soc., 1916, 110, ii, 655—656.

WHEN treated with hydriodic acid, morphine and codeine yield crystals which have always the same forms and allow of the differentiation of the two bases. A little of a salt of the base is sublimed by heating on an asbestos plate, and the sublimate covered with a cover-glass, at the edge of which a drop of hydriodic acid is then introduced. A slight granular precipitate is thus formed, and this disappears on heating. When the preparation is cooled, crystals of the tetra-iodide are formed immediately in the case of morphine, whereas with codeine, crystals of the tri-iodide are formed only after three to five minutes, but more rapidly in presence of a small drop of alcohol. The morphine tetra-iodide crystals are always very flat, quadrangular, mostly rectangular plates, on the average 30—50 μ broad by 80—120 μ long, and are of prismatic character and show direct extinction, and a blood-red to brownish-red colour. The bulk of the crystals are united to ladder- and step-like aggregates more than 1 mm. in length, and these in their turn are combined to stars and crosses. Pleochroism is either very slight or non-existent. Codeine tri-iodide crystals are paler, thicker, and smaller, the aggregates being not more than one-third of the size of morphine tetra-iodide crystals. Single crystals (20—50 μ , 40—80 μ) are very rare, and form half-moon-like triangles with a concave base and a blunted apex. The majority are twinned crystals, which always grow out on the convex side and give butterfly- and goblet-like forms, by which these crystals are recognisable at the first glance. Strong pleochroism is observed in this case.

Strychnine: Chemical and physiological action of — masked by quinine. E. Filippi. Arch. Farm. Sperim. Pharm. J., 1916, 97, 593.

WITH a mixture of quinine sulphate and strychnine nitrate, in which the former preponderates, a characteristic reaction for strychnine cannot be obtained with the sulphuric acid and potassium bichromate test. Crystals of strychnine picrate precipitated from such a mixture are not characteristic. In presence of an excess of quinine, strychnine no longer gives the physiological reaction with the frog. Death ensues, but the symptoms are quite distinct from typical strychnine reactions. The only rapid and accurate method is to precipitate the quinine as tartrate with sodium potassium tartrate, and apply the tests for strychnine to the filtrate.

Nicotine: Factors connecting the concentration and the optical rotatory power of aqueous solutions of —. A. Tingle and A. A. Ferguson. Trans. Roy. Soc. Canada, 1916 [iii], 10, 19—25. J. Chem. Soc., 1916, 110, ii, 656.

WORKING with a polarimeter using "j" light, the authors have carried out experiments which show: (1) that for solutions of concentration between 4 and 0.37%, the rotation of aqueous nicotine solutions is in simple inverse proportion to the concentration; (2) that the presence of potassium hydroxide and potassium salts has no influence on the rotation of nicotine salts; (3) that nicotine is not lost by vaporisation when an acid solution of nicotine sulphate is evaporated. In addition, the rotation, in terms of Ventzke sugar-scale divisions, of a pure specimen of nicotine in aqueous solution was determined, and found to be -1

division ($l = 200$ mm.) for every 0.2498 grm. of nicotine per 100 c.c. of solution, or 1 grm. of nicotine in 100 c.c. solution would read - 1.5 divisions in a 200 mm. tube for "j" light.

Phenylethylhydantoin (nirvanol), a new hypnotic and sedative. E. Wernecke. *Deut. med. Woch.*, 1916, 42, 1193—1194. *J. Chem. Soc.*, 1916, 110, i, 869.

77-PHENYLETHYLHYDANTOIN dissolves in 1650 parts of cold, and in 110 parts of hot water, and in 20 parts of alcohol; it has a hypnotic action of about the same intensity as phenylethylbarbituric acid (luminal), but is distinctly less toxic. Its hypnotic action is greater than that of diethylbarbituric acid (veronal).

Oxalyl chloride: Action of — on primary, secondary, and tertiary alcohols. R. Adams and L. F. Weeks. *J. Amer. Chem. Soc.*, 1916, 38, 2511—2519.

OXALYL chloride reacts smoothly with such primary alcohols as *n*-propyl, isoamyl, isobutyl, benzyl alcohols, etc., to give quantitative yields of the oxalic esters. Secondary alcohols such as phenylmethylcarbinol and menthol give the corresponding unsaturated compounds by the elimination of water, whilst in other cases small yields of ethers are formed. Tertiary alcohols mostly give the corresponding chlorides in good yield, but pinacene is converted into pinacoline and a smaller proportion of the carbonic ester of pinacene—G. F. M.

Amides: Pyrolytic decomposition of —. Parts I. and II. R. S. Boehmer, C. E. Andrews, and A. L. Ward. *J. Amer. Chem. Soc.*, 1916, 38, 2503—2507.

THE decomposition of acid amides into cyanides and water is greatly facilitated by the use of a contact substance such as alumina, sand, pumice, or graphite. The reaction may be carried out by heating the amide in a flask with about five times its weight of the contact material at such a temperature that the cyanide and water distil over whilst the unchanged amide condenses in the elongated neck and is returned to the flask, in which case dehydration to the extent of 50—70% is attained; or alternatively, an almost quantitative decomposition may be effected by carrying the vapours of the amide by means of a stream of air, over the contact material heated at about 425° C. in a hard glass tube.—G. F. M.

Nitroamines: Application of the nitrometer to the determination of constitution and estimation of nitrogen in a class of nitro-compounds. —. W. C. Cope and J. Karab. *J. Amer. Chem. Soc.*, 1916, 38, 2552—2558.

FURTHER evidence is adduced that the nitrometer reaction—liberation of nitric oxide by means of sulphuric acid and mercury—is not given by nitro-compounds in which the nitro-group is directly attached to carbon. On the other hand nitro- and nitroso-compounds in which these groups are attached to carbon through nitrogen, as in the nitro-amines and nitrosoamines, react like the nitrates and nitrites, giving a gas which was shown to consist entirely of nitric oxide. This class of substances, which includes nitro-urea, nitroguanidine, trinitrophenylmethylamine ("tetryl"), and all nitrosamines (but not such substances as *p*-nitrosodimethylaniline) may therefore be determined by means of the nitrometer, and in the case of unknown substances the nitrometer may be employed to determine whether the NO₂ or NO group is directly joined with

carbon or through a nitrogen atom. The nitrates of urea and guanidine behave anomalously, in that the nitrogen is not exclusively evolved as nitric oxide unless they are first converted into the respective nitro-compounds by treatment with concentrated sulphuric acid at 0° C. before introduction into the nitrometer.—G. F. M.

Halogenation. XIII. Methods of estimation of semicarbazide, semioxamazine, and oxalylhydrazide by their interaction with halogens and halogen oxyacids. R. L. Datta and J. K. Choudhury. *J. Amer. Chem. Soc.*, 1916, 38, 2736—2746.

WHEN semicarbazide and semioxamazine are treated with potassium bromate, iodate, or periodate and dilute sulphuric acid, carbon dioxide and 75% of the theoretical amount of nitrogen, along with ammonia, are obtained. Oxalylhydrazide gives carbon monoxide, carbon dioxide, and the whole of the nitrogen. The action of bromine or of hypobromite differs sometimes from that of the halogen oxyacids as regards the volume of gas evolved. Acidified chlorates and perchlorates are without action on semicarbazide or semioxamazine. Semicarbazide chlorate is violently explosive, and the nitrite decomposes giving a quantitative yield of urea.—F. C.

Chlorides of methane: Preparation of the lower — from natural gas. C. W. Bedford. *J. Ind. Eng. Chem.*, 1916, 8, 1090—1094.

IN the chlorination of methane intermediate compounds cannot easily be obtained unless the temperature is kept low, as otherwise the intermediate derivatives remain in the state of vapour and are chlorinated further in preference to the methane itself. As a means of accelerating the chlorination at a low temperature, light from the white flame are (this *J.*, 1916, 1211) proved very satisfactory. The reaction is accelerated by water, which serves to remove the reaction products and to bring the reacting gases into more intimate contact. The slightest trace of ammonia or similar nitrogen compounds stops the reaction at low concentrations of chlorine, and if a high concentration of free chlorine is used to overpower the negative catalyst a violent explosion results. In some experiments a wooden box, 28 in. × 28 in. × 41 in. inside, was placed with its open lower end in a vat of water and was filled with pieces of ice about the size of coconuts or larger. The box was closed by a clamped-on lid with a rubber gasket in between, and in one side was a glass plate through which the light from a white flame are passed. Air was displaced from the box by natural gas, and then the reaction was started by introducing chlorine in the proportion of about 1 vol. to 7 vols. of natural gas. As the reaction proceeded and the reaction products were condensed, the water rose in the box, and the introduction of further quantities of chlorine and natural gas was regulated according to the height of the water in the vat. The process was continued until the ice had sunk below the level of the window. The inside of the wooden box was coated with several layers of cellulose acetate dissolved in methylene chloride or chloroform to protect it from the action of chlorine and render the box gas-tight. The reaction product had little effect on the coating, for cellulose acetate is dissolved only by very pure methylene chloride or chloroform. In the apparatus described, 250 cu. ft. of natural gas was used in one experiment and the rate of consumption was from 14 to 30 cu. ft. per hour, several gallons of reaction product being obtained. The liquid product separating out under the water contained 35% of methylene chloride, 35% of chloroform, 3% of carbon tetrachloride, and 20% of chloro-ethanes. The portion dis-

solved by the water (14% of the total) was recovered by distilling off 5—10% of the water, the residue being about a 5% solution of hydrochloric acid. This soluble portion contained 61% of methylene chloride, 28% of chloroform, 1.5% of carbon tetrachloride, and 6% of chloro-ethanes. About 135 lb. of ice is required for 1 gallon of product. Methylene chloride can be made in large quantities by this process. It is an excellent solvent for cellulose acetate and closely resembles chloroform in properties. It is said to be superior to the latter as an anæsthetic. It is easily converted into chloroform by chlorinating in the presence of sunlight or the light from 150-watt tungsten lamps, the formation of carbon tetrachloride being avoided by chlorinating until only about 10% of the methylene chloride has been converted and then separating the chloroform by distillation. Up to 40% of methyl chloride is found in the gases removed from the ice chamber during the first few minutes after starting the reaction. It can be easily isolated by compression or by solution in water or other solvents.—A. S.

Peppermint oil; Effect of cultural and climatic conditions on —. F. Rabak. U.S. Bureau of Plant Industry, Prof. Paper 454.

A LIGHT sandy or loamy soil appears to be the most favourable for the production of peppermint oil of high quality. The yield of oil from fresh plants apparently decreases as the plant matures, but at the same time the percentage of esters in the oil, which impart to the oil its minty odour, increases. The menthol and ester contents of the oil are closely co-related. Drying the plants before distillation results in a considerable loss of oil, but the drying induces conditions favourable to producing esters, whilst the percentage of free and total menthol in oil from dried plants is also uniformly high. Drying also results in a considerable increase in free acidity. The formation of esters and menthol takes place most readily in the leaves and tops of the plants. The effect of shade is to decrease the formation of esters and of menthol, whilst frost has the reverse effect on the plants.

Lime juice; Concentrating — by freezing. Report of Agric. Dept., Dominica, 1915—46. Pharm. J., 1916, 97, 621.

RAW lime juice was placed in a receptacle of block tin or a glass jar, which was packed round with a freezing mixture of salt and ice. Ice separated on the side of the jar, and on continuing the process this layer gradually thickened until finally a solid mass was formed. The sides of the receptacle were warmed, and the solid mass removed, cut into pieces, and placed in the basket of a centrifugal machine. The mass was melted in stages whilst being centrifuged. The general conclusions arrived at are as follow:—Raw lime juice when frozen and treated in the centrifugal can be concentrated without affecting its properties as a beverage. If the juice is treated once only, the acid content may be increased from about 13 oz. per gallon to over 20 oz. per gallon. By repeating the process a juice containing 30 oz. per gallon can be obtained. The low testing juices can be converted into citrate of lime, thus eliminating all losses excepting those of handling. This process enables a very considerable saving to be made in freight, charges, and packages, amounting to between 40 and 60%.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Photographic plates and papers; Temperature coefficients of the action of monochromatic light on —. M. Padoa and L. Mervini. Atti R. Accad. Lincei, 1916 [v.], 25, ii., 168—171. J. Chem. Soc., 1916, 110, ii., 592. (See also this J., 1915, 1273.)

THE authors have exposed a photographic plate under a negative at 15° C., and at -85° C., to the action of the following lights: red, λ 650—620 μ ; yellow, 620—585; green, 550—530; violet, 437—394, and white, the plates used with yellow and green light being sensitised with ammonia, silver nitrate, and erythrosin, and those used with red light with aqueous-alcoholic pinachrome solution. The exposures were adjusted so that in all cases positives of equal intensity were obtained on development with one and the same developer for equal periods of time. With each light the temperature-coefficient of the action of light on the plate is 1.05. The direct blackening of so-called citrate paper by white, blue (λ 470—490), and ultra-violet light (λ 100—350) at 15° C. and -85° C. was also investigated, the corresponding temperature-coefficients being 1.16, 1.49, and 1.07 respectively. The varying behaviour with the plates and papers seems to indicate that the formation of a latent image on the plate is not due to a photochemical process consisting in the decomposition of silver chloride into its elements.

PATENTS.

Silver from weak photographic emulsions; Recovery of —. F. F. Renwick, Brentwood, B. V. Storr, and Ilford Limited, Ilford, Essex. Eng. Pats. (A) 16,708, Nov. 26, 1915, and (B) 102,168, Nov. 26, 1915. (Appl. No. 683 of 1916.) Addition to Eng. Pat. 16,708 of 1915.

(A) VERY dilute photographic emulsions, in which the silver salt is too finely divided to settle from the gelatin solution, and which are too poor in silver for treatment by the usual recovery processes, can be concentrated by the action of suitable precipitants. The addition of small quantities of ferric, copper, or aluminium salts produces a precipitate of a gelatin compound which carries down the silver salt with it. The exact quantity of precipitant is dependent on the concentration of gelatin in the liquor and on the temperature, larger relative quantities being required for weaker liquors or at higher temperatures. In the example given, a liquor containing 0.2% of metallic silver as halide and about four times that quantity of gelatin required the addition of about 0.025% of ferric chloride for precipitation. Acidity of the liquor or excess of the precipitant or a temperature above about 86° F. (30° C.) prevents the reaction

Alkalinity of the liquor necessitates the use of a greater quantity of the precipitant, and the addition of alkali will cause precipitation to occur where too much precipitant has been added. Freshly made liquors require to be aged by cooling to about 45° F. (7° C.) or by standing for about a day at normal temperature in order to be precipitable by these salts. Precipitation of the gelatin and silver salt may also be obtained by addition of ordinary gelatin coagulants such as picric, chromic, and tannic acids, but much larger quantities are required than with the metallic salts mentioned. Ageing is not necessary and excess of the precipitant does not interfere. (B) The concentration of the silver salt may be produced by the addition of two or more substances interacting to form a precipitate which carries down the silver salt but little or no gelatin. Suitable precipitates are aluminium and ferric hydroxides, resin, and casein. Considerably larger quantities of precipitants are required than by the use of the metallic salts mentioned in the chief patent.—B. V. S.

XXIII.—ANALYSIS.

Microscopy: Quantitative —. T. E. Wallis. Analyst, 1916, 41, 357—374.

A METHOD described for the quantitative microscopical examination of mixed powders depends on the addition of a substance consisting of uniform grains and then determining the ratio of the constituents to the added grains. The details of the method are as follows:—A mixture of equal weights of the pure substance under examination and of the adulterant is prepared; 0.2 gm. of this mixture is mixed with 0.1 gm., or other suitable quantity, of lycopodium and sufficient of a suspend-

ing fluid (this may be an oil, soft paraffin, glycerol, or other suitable liquid) to produce a liquid of which 1 drop, when mounted and examined with a one-sixth inch objective, will show from 10 to 20 lycopodium spores in each field. In most cases this will be attained when the volume is about 20 c.c. A drop of the suspension is transferred to a slide, a cover glass is applied, and the numbers of particles of adulterant and of lycopodium spores are counted in ten different fields. Another drop is then mounted, and counts are made. The ratio of the number of lycopodium spores to the number of characteristic elements of the adulterant is expressed as a percentage of the lycopodium spores; the results of the two counts should not differ by more than 10%. A quantity of 0.2 gm. of the actual sample is then mixed with 0.1 gm., or other suitable quantity, of lycopodium and about 20 c.c. of the suspending fluid, drops are mounted on each of two slides, and counts made. The results of the counts are expressed in the same way as in the case of the standard mixture. The numbers obtained for the foreign ingredient are directly proportional to the amounts present and a simple calculation gives the quantity. Unless the powders have been dried previously, a correction must be applied for moisture. The method is applicable to a large variety of mixtures, including starches, food products, and drugs, of which examples are given. Even in the case of a mixture of two starches the addition of lycopodium is an advantage, since greater precision is secured.—W. P. S.

Radioactivity: Determination of —. F. B. Furber. J. Assoc. Off. Agric. Chem., 1916, 2, 116—119.

IN making measurements of low radioactivity, the radium emanation was separated from the substance under examination and its effect on an electroscope compared with that produced by a known amount of radium. In the case of waters, the emanation was separated by boiling; soluble substances were dissolved in water or acid, and insoluble substances were fused with alkali carbonate, treated with water, and the solution then acidified. For separating and collecting the emanation Boltwood's apparatus (Amer. J. Sci., 1904, 18, 378; Phil. Mag., 1905, 9, 599) has been found very satisfactory. An alternative method consisted in bubbling air through the heated solution. The gases obtained were kept for 10 minutes, to allow for the decay of any thorium emanation, and then transferred through a calcium chloride tube to the discharging chamber of an emanation electroscope. Some samples of artificial waters and medicinal preparations examined were found to be radioactive, as claimed on the label, but in other cases the radioactivity was so slight as to be negligible.—W. P. S.

Sulphate: Quantitative determination of small quantities of —. H. J. Hamburger. Proc. K. Akad. Wetensch. Amsterdam., 1916, 19, 115—125. J. Chem. Soc., 1916, 110, ii., 611.

THE micro-volumetric method, already applied in the estimation of small quantities of potassium (this J., 1916, 277), has been found to yield satisfactory results in the estimation of sulphate by precipitation as barium sulphate. The precipitate is forced into a calibrated capillary tube by centrifuging, and when constant the volume of the precipitate is read off. The tube is calibrated by preliminary experiments with solutions containing known quantities of sulphate. Experiments showed that the volume of a given quantity of precipitated barium sulphate, depends on the size and shape of the crystals, and it has been found necessary to carry out the precipitation under certain definite conditions. In particular, it is

essential that the precipitated barium sulphate should consist of very small crystals, and this result may be attained by the addition of acetone. The procedure adopted is to add 2.5 c.c. of hydrochloric acid (1 : 1) to 5 c.c. of the sulphate solution : to this solution is added 5 c.c. of a barium chloride solution (2.4% $\text{BaCl}_2 \cdot 2\text{H}_2\text{O}$) containing three to five drops of acetone. When the estimation is carried out in this manner, the result obtained is not affected by the presence of sodium, potassium, calcium, magnesium, chloride, or phosphate in the original solution.

Methylene Blue: Use of—*as a reagent in chemical analysis.* Application of the process to the detection and determination of perchlorates in Chile saltpetre. A. Monnier. Arch. Sci. phys. nat., 1916 [iv], 42, 210–216. J. Chem. Soc., 1916, 110, ii., 639–640. (See also Attack, this J., 1915, 1005.)

THE following acids in dilute solutions, preferably in the form of their alkali salts, give coloured, crystalline precipitates with a solution of Methylene Blue. Hydriodic acid gives a deep blue precipitate, showing bronze-green by reflection; perchloric and hydroferrieyanic acids, violet precipitates, bronze-green by reflection; persulphuric, dichromic, and permanganic acids, rose-violet precipitates, bronze-green by reflection; metavanadic, molybdic, and tungstic acids, deep blue precipitates. The precipitate with a persulphate is readily distinguished from that with a perchlorate in that the former when calcined leaves a slight residue showing the reactions of a sulphate, and the latter when heated decomposes violently with deflagration. The amount of potassium perchlorate can be readily estimated colorimetrically in a sample of Chile saltpetre by this method. To 20 c.c. of a 5% solution of the crude nitrate 1 c.c. of a 0.3% solution of Methylene Blue in water is added, and the mixture left overnight. A crystalline precipitate forms, and the supernatant liquid is tinted blue. This colour is compared with that of standard tubes containing varying amounts of pure potassium perchlorate. If the perchlorate is present to the extent of less than 0.2%, a 10% solution of crude nitrate, and if more than 0.5%, a 2.5% solution of crude nitrate is used. If the crude nitrate contains any iodide, this can be first removed by shaking the solution with moist silver oxide.

Trade Report.

Prohibited exports. Orders in Council, Dec. 12 and 19, 1916.

The following headings are deleted: (1) Manganese peroxide of, (2) scheelite, (2) wolframite, (2) stron-

tium sulphate, (2) lead, pipe, scrap, or sheet, and solder containing lead. The following headings are added: (3) Formates, not otherwise prohibited, (3) iridium, osmium, palladium, rhodium, and ruthenium, compounds, (3) white lead, (1) manganese peroxide, and mixtures and preparations thereof, (3) oxalates, not otherwise prohibited, (3) soda lime, (3) sulphites, metallic, not otherwise prohibited, (3) thiosulphates, metallic, not otherwise prohibited, (1) zirconium compounds, (3) glue, osseine and concentrated size, fish glue, isinglass, finings and other kinds of gelatin, (3) Iceland, Irish and sphagnum moss, algin and its compounds, (3) iridium, osmium, palladium, rhodium, ruthenium, and alloys of these metals, (2) lead (except pig lead), alloys of lead, solder containing lead, and manufactures of lead and its alloys, not otherwise prohibited, (1) thorium and its alloys, (1) zirconium and its alloys, (2) oil varnishes, (1) wood pulp, (2) zirconium minerals, (1) strontium compounds, and mixtures containing strontium compounds, (2) tungsten ores (including ferberite, hubnerite, scheelite, and wolframite), (3) wines.

Note. The exportation of the goods mentioned above is prohibited as follows:—Goods marked (1), to all destinations. Goods marked (2), to all ports and destinations abroad other than ports and destinations in British Possessions and Protectorates. Goods marked (3), to all destinations in foreign countries in Europe and on the Mediterranean and Black Seas, other than France and French Possessions, Russia, Italy and Italian Possessions, Spain, and Portugal, and to all ports in any such foreign countries, and to all Russian Baltic ports.

Exports to Switzerland.

The Contraband Department of the Foreign Office has forwarded the following additions to and corrections in the list of articles in respect of which licences for export to Switzerland are only granted if the goods are consigned to the Société Suisse de Surveillance Économique (S.S.S.).

Additions to list. Abaca and similar fibres, Cadmium in all forms. *Changes in the details of items already on the list.* Bones, whole, dissolved, melted, calcined, or bone ash. Naphtha; naphthylamine (alpha and beta naphthylamine); naphthol (alpha and beta naphthol) and similar products; naphthalene and its compounds. Skins, raw and dressed, including fur skins not put together. Soap, including "Monkey Brand" soap. Perfumed toilet soaps.

Small parcel scheme. The following articles have been withdrawn from the benefits of the small parcel scheme, and should therefore no longer be printed in italics:—Benzoates of benzyl and of ethyl. Calcium cyanamide. Carbide of calcium. Cellulose. Condensed milk, sweetened or not. Hydrobromic acid. Infusorial earth. Mercury, and its compounds and preparations, and mixtures containing such compounds of mercury. Packings, engine and boiler, including slag wool. Salts of thorium and of cerium and other salts of rare earths. Slag wool. Sulphate of zinc. Titanium, metal and salts.

Contraband of war. Royal Proclamation, Dec. 29, 1916.

The following articles are declared absolute contraband:—Oxalic acid and oxalates. Formic acid and formates. Phenates. Metallic sulphites and thiosulphates. Soda lime and bleaching powder. Platinum, osmium, ruthenium, rhodium, palladium, iridium, and the alloys and compounds of these metals. Strontium salts and compounds thereof. Sulphate of barium (barytes). Bone black.

The following amendments are made in Schedule I. of the Royal Proclamation of the 14th October,

1915 (see this Journal, 1915, 1075):—For item 8, "ethyl alcohol; methyl alcohol," there is substituted "Alcohols, including fusel oil and wood spirit, and their derivatives and preparations." For item 35, "aluminium, alumina, and salts of aluminium," there is substituted "aluminium and its alloys, alumina, and salts of aluminium." For item 11, "wolframite, scheelite," there is substituted "tungsten ores."

In Schedule II. of the same Proclamation, for item 5, "fuel, other than mineral oils," there is substituted "fuel, including charcoal, other than mineral oils."

Books Received.

A TEXT-BOOK OF QUANTITATIVE CHEMICAL ANALYSIS. By A. C. CUMMING and S. A. KAY. Second Edition. Gurney & Jackson, 33, Paternoster Row, London. 403 pages, 8½ × 5½ in. Price 9s.

No fundamental alteration has been made in the arrangement of this useful book, the first edition of which appeared in 1913, but the text has been revised throughout, and new methods and exercises included. The book is divided into ten parts, as follows: I. General principles. II. Volumetric analysis. III. Gravimetric analysis. IV. Colorimetric methods. V. Systematic quantitative analysis. VI. The analysis of simple ores and alloys. VII. Gas analysis. VIII. Water analysis. IX. Quantitative analysis of organic substances. X. Determination of molecular weights. The volume concludes with an appendix and indexes.

DYEING IN GERMANY AND AMERICA. Second edition. By S. H. HIGGINS. Longmans, Green & Co., 39, Paternoster Row, London, E.C. 143 pages. 8½ × 5½ in. Price 5s.

THIS book, of which the first edition appeared in 1907, gives a general survey of the dyeing and allied industries of the United States and Germany, the material for which was collected during a tour of these countries in 1905-6. No further visit has been paid to either of these countries, but a considerable amount of new matter has been added as a result of experience gained in the dyehouse of the Municipal School of Technology, Manchester, and later as chemist and manager of a bleaching works. The last chapter of the first edition, on colour production, has been left practically unaltered, and a further chapter has been added containing a description of some recent developments in this branch of industry.

THE PORTLAND CEMENT INDUSTRY. By W. A. BROWN. Crosby, Lockwood & Son, 7, Stationers' Hall Court, London, E.C. 158 pages, 8½ × 5½ in. Price 7s. 6d.

A CONCISE description is given of the processes and plant used in the manufacture of Portland cement, and the methods of testing. The book is illustrated by 36 plates and 12 figures.

BULLETIN OF THE IMPERIAL INSTITUTE. Vol. XIV. No. 3. July to September, 1916. Price 2s. 6d.

THIS issue of the Bulletin contains the results of investigations in connection with recent work on monazite and other thorium minerals in Ceylon, the new coalfield in West Africa, the essential oil of Sherungulu tubers (2nd article), lemon grass oil from India, Ceara rubber from Nigeria, and fibres from the Belgian Congo. There are also general articles on the occurrence and utilisation of antimony and cobalt ores, and the cultivation of the pine-apple for fruit and fibre.

No. 2, Vol. XXXVI.

Official Notices.

NEW YORK SECTION.

Dr. Parker C. Mellhiney has resigned the Secretaryship of the New York Section, a position which he has occupied with conspicuous success for the past 6½ years. He will be succeeded by Dr. Allen Rogers of the Pratt Institute, Brooklyn, N.Y. The Council at its last meeting passed a resolution expressing appreciation of the services rendered by Dr. Mellhiney to the Society.

BEIT FELLOWSHIPS FOR SCIENTIFIC RESEARCH.

The Trustees for the Beit Fellowships for Scientific Research announce that the next election of Fellows will take place on or about July 15th, 1917. Not more than three Fellowships will be awarded. Applications must be received on or before April 16th, 1917. Forms of application and all information may be obtained, by letter only, addressed to the Rector, Imperial College, South Kensington, London, S.W.

These Fellowships, of which the annual value is £150, are tenable for one year, but may be extended by the Trustees for a further period not exceeding one year. Every Fellow must be a person of European descent by both parents, but otherwise of any nationality, who at the date of election shall have taken a degree in any Faculty in any University in the British Empire approved by the Trustees, or is in possession of any Diploma or Associateship of any College approved by the Trustees. The holding of any other Scholarship or Fellowship will disqualify an otherwise eligible person. Candidates must be under 25 years of age at the time of election, and must state in their applications the general nature of the research which they propose to carry on. Fellows will be attached to a department of the Imperial College of Science and Technology and will work under the supervision of a Professor.

Editorial.

THE JOURNAL.

At the informal meeting of the London Section, held on December 19th last, a report of which appears on pages 63—65 of this issue of the Journal, there was a certain amount of criticism on the character of the Journal, to which some reference may be made here. The Journal consists broadly of two parts, for one of which—the original matter—we have to depend upon our members, whilst for the other the editorial staff is responsible. The original papers and communications should form the salient feature of the Journal, and the standard of these, both as regards quality and quantity, has been maintained at a consistently high level during recent years, although some falling off might have been anticipated during the period of industrial disturbance following the outbreak of war. At the same time, the members of a Society numbering over 4000 might reasonably be expected to provide more papers than is the case at present, and it is to be hoped that members will use every effort to provide or secure suitable matter for the Journal. Communications to the Society serve a twofold

purpose, for in addition to supplying material for the Journal they provide the wherewithal for meetings of Local Sections. In many of our Sections it has been found increasingly difficult of late to induce members to come forward with communications. There appears to be a mistaken idea that all papers must contain the results of some original research. This is far from being the case. Some of the most interesting papers which have appeared recently have been those in which nothing of an absolutely novel character is described—for example, some of the papers read at our last annual meeting in Edinburgh. At the meeting of the London Section referred to, it was suggested that papers or discussions on such subjects as labour in chemical works, and filtration problems, would be of great general value, and many other subjects suggest themselves, such as descriptions of various types of chemical plant (still, evaporators, etc.) and their suitability for different kinds of work. In every works, too, there are unusual occurrences and small problems which are worthy of note and will undoubtedly prove very interesting and suggestive to others. If any member has notes of matters such as these, which could be worked up into a paper, however short (and brevity is no objection), he is requested to communicate with the Secretary of his Local Section, or if he is not a member of a Section, with the Editor.

Another point in connection with original papers which calls for remark is concerning the discussions. Although comparatively very few members take part in these discussions there are probably many who have some interesting observations to make on the various papers, but who for a variety of reasons do not do so; and again, many members must find matter for comment in papers which they read in the Journal. The Editor will be glad to receive any remarks or comments by way of discussion on any paper which has appeared in the Journal or has been read at a Sectional meeting.

The abstracts in the Journal have from time to time been the subject of criticism from various standpoints. On the one hand it is sometimes urged that they are not full enough nor informative enough, but it must be pointed out that no abstracts can be sufficiently full to meet the requirements of those to whom the particular matter appeals directly. They are merely intended to indicate to those interested whether or not the matter in the original paper or patent specification is of sufficient importance to justify further reference to it. Again, some members have stated that only one or two pages of the abstracts, perhaps, in each issue of the Journal are of interest to them. Whilst it may be true that this is the proportion of matter which refers directly to some particular industry, it cannot be urged too strongly that members should peruse the abstracts of literature dealing with other industries than those with which they are connected, for not only will they find a large amount of general information in these sections, but they will undoubtedly come across many items which, though not bearing directly upon their own industry, will suggest the application therein of a new process or piece of apparatus, or in some other way furnish a useful idea.

In conclusion, members are invited to make suggestions as to the directions in which the value and utility of the Journal could be enhanced; any such suggestions will be very welcome and will receive careful consideration.

Glasgow Section.

Meeting held at Glasgow on Tuesday, November 28th, 1916.

MR. JAMES MCLEOD IN THE CHAIR.

A LABORATORY GAS METER.

BY E. G. BECKETT.

It is often of interest to know the rate of a stream of gas employed in a laboratory operation, and as the following device has been found to be useful for this purpose, it was thought that a description of it might be helpful to other workers.

The diagram shows the design of the apparatus. It is filled up to the dotted line, AB, with water, which thus fills the siphon, C, connecting the two limbs of the U-tube. When the gas to be measured enters the apparatus, it forces the level of the water down in A and up in B until the difference in pressure causes the siphon, C, to empty itself into B. The gas in A then escapes into B through the siphon, while the level of the water readjusts itself in the U-tube and fills the siphon, C. The process then starts again. The siphon runs over each time after a definite amount of the gas has passed through the instrument, which amount, however, varies with the velocity of the gas. A determination of the capacity of the gas-meter for different velocities gave the following results:—

Rate, c.c. per sec.	Capacity in c.c.
15.5	41.5
10.0	42.5
7.61	40.5
6.56	40.0
3.75	37.5
1.93	36.5
0.51	35.1

As this siphon gas-meter is made entirely of glass, it may be used for any gas which is slightly soluble in water or in the liquid used. It is especially useful for highly corrosive gases, such as chlorine, for which the ordinary metallic gas-meter is out of the question.

If a constant stream is desired, gas at a high pressure should be employed, and the rate regulated or throttled immediately in front of the gas-meter. For gases very soluble in water, other liquids have

to be used instead, but only mobile liquids can be employed.

This apparatus can be obtained from Messrs. Baird and Tatlock, London.

I desire to thank Messrs. Nobel's Explosives Co., Ltd., for permission to publish this communication.

London Section.

Meeting held at Burlington House on Monday, December 4th, 1916.

MR. ARTHUR R. LING IN THE CHAIR.

In the absence of the authors, the following paper was read by Mr. J. A. Reavell.

PRODUCTION OF NITRATE OF SODA IN CHILE—PAST, PRESENT, AND FUTURE.

BY I. BIRKWOOD HOBSBAUM, A.M.S.T., AND J. L. GRIGIONI.

For an industry of such enormous dimensions and importance as the nitrate industry of Chile, very little text book information is available: nor can its progress be followed by the illustrious names coupled with steps of true importance which in other industries mark the grappling ground, where industrial problems are overcome by science. That is not to say that the nitrate industry has been in the hands of mediocrities throughout its history, but it must be freely admitted that its progress hitherto has been more commercial than scientific, and that its real development on scientific lines is yet to come.

There arises in all industries, especially in those in which the prime material is directly obtained from natural deposits, a crisis at some time, which no purely commercial ingenuity can overcome. When labour is reduced to its minimum cost, transport, both of raw material and finished product, as cheap as possible, selling price pushed to its economic limit, and mechanical device as satisfactory as can be expected, little more hope remains to an industry save that science can find a means of increasing efficiency or improving it in such a way that poorer, and necessarily cheaper, raw material may be used. We do not state that such is the position actually held by the nitrate industry, but that such a position is within sight. The richest of the known deposits have been used up: the medium deposits are being eaten into yearly, and yet the poorer deposits are practically untouched and only waiting for human ingenuity to devise the necessary means for making them useful.

We propose in this paper to trace the progress of the nitrate industry from the discovery of the deposits to the present day. We propose to analyse this progress—to point out the directions in which the methods of refining have been modified and brought up to date—to adumbrate the deficiencies caused by these types of modification and to show that even when the acme of mechanical efficiency is reached, the process still remains comparatively primitive. We will then describe the newer schemes by means of which it is hoped to put the nitrate industry on a level with well-organised industries. These introductory remarks will be made all the clearer when it is appreciated that the commercial preparation of nitrate of soda from the raw material, in which it naturally occurs, is essentially a mechanical problem of lixiviation (and separation of solution from solid) followed by a physico-chemical

problem of crystallisation. Caliche, as the naturally occurring nitrate-containing mineral is locally called, is essentially a mixture in which a variable amount of insoluble matter is bound together with crystals of soluble salts, the whole forming a conglomerate.

The composition of some typical caliches is shown in Table A.

TABLE A.
Analyses of caliches.

Insolubles	15.677	20.213	13.9	34.597	42.213	51.934	50.543	62.938
Totals	99.945	99.943	99.989	99.992	99.992	99.922	99.951	99.981

It is not the intention of the authors to deal with the question of the origin of the deposits, nor with the methods of mining. A few remarks on the latter will appear towards the end of the paper, but enough has already been written on this part of the subject by others, and so little development has taken place since, as to leave what has been written quite up to date.

Since the use of Chilean nitrate was brought to notice in 1809 by Taddeo-Haenke, a German domiciled in Bolivia, the essential principle of the commercial method of separating the soluble from insoluble matter has not been altered. It might be broadly stated that from 1809 onwards the endeavour has been to prepare a concentrated solution of nitrate of soda by boiling the raw material with water and mother liquor for some time and running off such solution when a convenient maximum temperature and density are reached. Dependent upon this temperature is the relative quantity of nitrate of soda, salt and other impurities which are retained in solution.

The increase of solubility of nitrate of soda with rise of temperature and the decrease of solubility of sodium chloride in such a solution of nitrate, is such that an effective separation of the two salts can be brought about by this means and the liquors thus obtained, when allowed to crystallise, will deposit, as crystal, little or no sodium chloride. To follow adequately the progress of the industry from its inception it will be necessary to trace, through certain periods, the carrying out of the above outlined desideratum. These periods have no other significance than ease of classification for descriptive purposes.

1st Period, 1809-1856: 2nd period, 1856-1880: 3rd period, 1880-1900: 4th period, 1900-present day. The total production up to 1915 has been approximately 51,000,000 tons.

During the first period—1809-1856—which was the unorganised period of the industry, the nitrate bearing grounds lay in the three countries on the West Coast of South America, Peru, Bolivia, and Chile. As little importance was attached to these deposits at that time, and the workings were carried on under the most primitive conditions, it can easily be understood that nothing but practically the purest of the caliche was taken out of the ground to be refined. It is probable that the raw material worked contained as much as 80 % or more of nitrate of soda. The

nitrate of soda contained in the caliche was brought into solution by boiling the latter with water in copper pans (of native manufacture) heated by direct fire, the fuel employed being "carbonized wood." The liquors obtained were run off and the solid refuse disposed of. By virtue of the richness of the raw material one lixiviation with water and returned mother liquor

was enough to produce sufficient solution to be run off, from which comparatively pure nitrate of soda could be crystallised by gradual cooling in tanks exposed to the air.

During the years 1810-1812 six or eight of these primitive establishments were erected, which were able to produce between March, 1812, and January, 1813, 22,723 Spanish quintals of nitrate (roughly 1000 tons). In 1830 the value of this product as a fertiliser began to be recognised in Europe and the industry began to improve its output; thus from 1830-1834 production was 361,386 quintals, from 1850-1854 3,260,492 quintals.

TABLE I.
Increase of exports of nitrate of soda from Chile, from 1830 to 1880.

Period 2, 1856-1880. Although we have chosen to mark the year 1856 as the beginning of a new period we have done so for sentimental reasons more than any other, because although it marks officially the introduction of steam into the process, the full value of this innovation was not taken advantage of, save in very few works, until very much later. The modification, involving the use of steam, was the leading of the steam through perforated pipes into the mixture of caliche and liquor. Only about 60% yield was obtained, the "dumps" from these "parados," as they were locally known, containing 20-30% nitrate and the fines (or borras) about 40-50% after washing.

During this period the raw material used fell little short of the high percentage of nitrate above referred to and it may be stated on the authority of observers of that time that material of lower contents than 50% of nitrate of soda was not taken to the works for treatment. Table 1 shows the development of the export of nitrate of soda from 1830 until 1880. During this period the majority of the works were situated in the province of Tarapaca, which belonged to Peru, but was annexed by Chile as a result of the war which began in 1879 and was concluded by the Treaty of Ancón in October, 1883. Thus practically at the opening of the third period the nitrate bearing grounds of South America were in the hands of that most progressive of South American States—the Republic of Chile. As we have said, from 1856 onwards the means of producing nitrate of soda began to be divided between the works of the essentially primitive type, in which the pans were fire-heated and those representing the first step forward, in which the nitrate was dissolved in tanks by heat supplied by the introduction of steam through perforated pipes.

All this so far was the treatment of an exceedingly high grade material by boiling with water (and returned mother liquor) for the preparation of the concentrated solution for crystallisation. During this period also closed serpentine coils were introduced into the tanks through which coils passed steam from the boilers. This was of course the natural corollary to the perforated pipes as it avoided dilution of liquors by condensed water.

Period 3, 1880-1900. In 1876 a very radical change was introduced into the process and from that date the system adopted has not been varied, save for minor modifications and mechanical improvements. The honour of introducing this vital alteration belongs to Mr J. T. Humberstone, who is affectionately known in the nitrate districts as the "father of the nitrate industry."

He applied the counter-current system of lixiviation in tanks, which he adapted from the alkali makers in England, and which is known locally as the "Shanks system." In this system of counter-current lixiviation, the raw material is treated with the richest liquor and the successive stages with weaker liquors, the last wash being done with water. The temperature is highest in the richest tank and lowest in the tank receiving its final wash.

The liquors pass forward through a series of tanks in which they are strengthened up by lixiviating richer material, and the temperature in each forward tank is increased. The heating is done by means of closed steam coils, the condensed water from these being returned direct to the boilers. The effect of the introduction of such a system permitted of the disposal of the refuse insoluble material, with a much smaller content of nitrate of soda than heretofore owing, naturally, to the greater proportion of water which could be used in the lixiviation process. It had an all-round cheapening effect upon the production cost of the finished product, and permitted where necessary the exploitation of mixed deposits of poorer ley. It permitted the mixing of material of 60% nitrate

content with that of 30%, or 50% with 30%, but even at this period it was not considered advisable to remove from the grounds material of less than 30%. From this time onwards the newer system gained a very rapid following and was adopted by the English companies to whom the development of the industry was at this time most due, and in 1882 the Liverpool Nitrate Co. instructed Mr. (now Sir) Robert Harvey to prepare plans and estimates for the construction of their oficina "Ramirez." The details of this works were communicated to the Institution of Civil Engineers by Sir Robert Harvey in 1884 and by courtesy of this gentleman we are able to extract from his paper some of the important details of this then, then, largest works in Chile. We are indebted also to Sir Robert Harvey for much information regarding the processes in use prior to introduction of the Shanks system.

Ramirez Works, 1883. Extract from Minutes of Proceedings, Institution of Civil Engineers, Harvey (Nitrate of Soda 1884/5).

Six steel boilers, 30 ft. x 6 in., double flues, with 6 Galloway tubes, 12 boiling tanks, 30 ft. x 8 in. x 7 in. (1680 cub. ft. capacity each), with steel heating tubes; 90 crystallizing tanks, 16 ft. x 16 ft. x 3 ft. deep, sloping to 2 ft. 9 in. (736 cub. ft. capacity); 2 feeding tanks, a 5 compartmental washing tank, and 3 circular tanks, 25 ft. in diam. by 12 ft. high. Locomotives and rolling stock of 2½ miles of portable railway, by John Fowler and Co., of Leeds. Engines, pumps, machine tools, by Tangye Bros., and 3 crushing machines.

This works was erected by Sir Robert Harvey, and completed in 1884. The author says: "In order to provide caliche sufficient to meet the requirements of so large a system of machinery at least 250 mules and 40 carts would be required." To avoid this expense he introduced the innovation of a portable railway with two locomotives and eighty side tip cars and only used 30 mules and 5 carts for taking the caliche to the side of the railway line which runs out 1½ miles in the caliche quarries. The line has a 2 ft. gauge, 16 lb. rails; the cars carry 1½ tons of caliche. The works were built for a production of from 6000 to 6500 tons of nitrate of soda per month and the author mentions that the chemical analysis of his raw material was: Nitrate of soda, 51%; common salt, 26%; sulphate of soda, 6%; sulphate of magnesia, 3%; insoluble, 14%.

The cost of the machinery, plant, and construction amounted to £110,000 and for every 1 ton of coal burnt, 12 tons of nitrate of soda was manufactured. It is a far cry from 1884 to 1914, but during this period of 30 years no further alteration has been made in the process than the introduction of certain labour-saving devices, such as belts and bucket elevators, electrically driven machinery, the use of oil fuel for generating steam, and the introduction of Diesel engines. That is to say every improvement has been in the direction of perfecting the mechanical side of the system.

Table 2 will show the increase in export of nitrate of soda from 1880-1900.

Period 4, 1900-15. In 1911, an English nitrate company began the construction of a new oficina from the design of Messrs. Strain and Robertson, Consulting Engineers, Glasgow. This works was designed for an output of 90,000 qtls. nitrate per month from material containing 25% nitrate of soda.

In this works the whole of the power for crushing and distribution of crushed material and for pumps was provided by a central electrical generating station containing two 200 B.H.P. Diesel engines by Willans and Robinson and two 3-phase alternators by Siemens Bros. direct coupled. For the transmission of power to the wells and outlying places step-up transformers are used and the current transmitted by bare copper aerial lines.

The steam for process work was generated by Lancashire boilers (30 ft. \times 7 ft. 6 in.) fired with oil fuel, of which 5 were installed.

The material was crushed in Blake Marsden crushers (24 in. \times 18 in.), driven electrically, five of these crushers being installed.

TABLE 2.

Increase of exports of nitrate of soda from Chile, 1880 to 1900.

The crushed material was elevated to the boiling tank stage by belt conveyers and distributed by belt to the tanks for loading. There are 18 boiling tanks, each 34 ft. \times 7 ft. 6 in. \times 8 ft. 6 in., provided with false bottoms 1 ft. above true bottom and fitted with the necessary connections for transference of liquors and three "ripio" discharge doors for discharging the spent caliche. The latter is drawn to the dump tip in side-tipping waggons drawn by petrol locomotives. The works is equipped with 154 crystallizing tanks, each 18 ft. \times 18 ft. \times 3 ft. 6 in., sloping to 3 ft., the whole of these mounted on a substantial steel structure. The raw caliche is brought into the works by a light railway 2 ft. 6 in. gauge, 35 lb. rails spiked being used.

The mileage of railway is 2-2½ miles, and the loading stations are fed by carts and mules from the actual mining localities.

The water supply is derived from wells, as is usual in these districts, the power for pumping being supplied from the central station.

The works is provided with a very complete engineering workshop fully capable of dealing with all necessary repairs for the efficient upkeep of so large a mechanical installation. It also has a small foundry for both brass and iron.

The details of this oficina as compared with the details of that constructed by Harvey in 1884 show that the power and mechanical side of the works have been completely modernised, with the result that lower grade material and consequently increased proportional amounts thereof can be commercially handled.

A description of one month's working will help to show what has been effected by the modernisation of the means of handling the large quantity of raw material.

During the 29 days worked in one particular month there were brought in 12,484 cartloads of raw material; estimated weight of cartload 41 Spanish quintals (101.2 lb.). Fifteen carts were employed in feeding the loading stations, each making about 28 trips per day. 2 locomotives and 65 side tip waggons were used to transfer the material from the loading stations to the treatment plant.

The raw material averaged 21.89% nitrate and the total treated—499,544 Spanish quintals—was divided into 350 charges (tank loads) of about 1430 qtls. each and the yield showed, on the figures taken, an efficiency of 56.4%.

The figures are as follows:—

Total caliche 499,544 qtls. at 21.89% nitrate = 109,350 qtls. nitrate.
Produced 65,000 qtls. of 95% nitrate = 61,750 qtls. nitrate.

In ripio 400,614 (dry weight at 5.04% estimated)	20,192.45 qtls.
In borra 33,900 at 17.45	5,915.55 ..
Unaccounted for	21,492.00 ..
	<hr/> 47,600.00 ..

That is a recovery of 56.4% of the nitrate contained was effected from raw material of about 22%.

For each quintal of petroleum consumed 7.98 quintals of nitrate was extracted, or in coal equivalent (taking the heat efficiency oil to coal as 18 to 12) one qtl. of coal produced 5.32 qtls. of nitrate.

Considering this figure of 1 to 5.32 coal for nitrate against that of 1 to 12 as obtained in 1884 it would seem as though no improvement at all had taken place during this period. It is necessary, however, to consider that in 1884 the material used contained 51% nitrate and 14% insoluble, while in 1914 the proportions were 21.89% nitrate and 45.00% insoluble, and that 1914 material could not have been treated by 1884 means.

The fuel cost for haulage of the increased quantity of raw material and discharge of the increased quantity of insoluble matter ought to increase in the proportion corresponding to the fact that 1000 tons caliche in 1884 becomes 2330 tons in 1914 to supply the same quantity of nitrate to the plant, i.e., haulage, loading, and treatment alone ought to increase fuel consumption in the proportion of 1:2.33 and costs of discharge of refuse ought to increase in proportion to the increase in insoluble residue. Hence without mechanical improvement the 1 to 12 might easily have been expected to have fallen to 1 to 2 in 1914. Thus the economy of fuel is one of the salient features of the modern plant as against the old type.

Method employed in the refining of Chile saltpetre from the raw materials.

In the most modern of the Chilean works the methods adopted to-day actually differ very little from those used 30 years ago. The raw material is passed through crushers of the Blake Marsden type and lifted to the boiling tanks either by belt conveyor, bottom emptying car and hoist, electrical or hydraulic, or drawn up an inclined plane in a side tipping or bottom emptying car. Where a belt conveyor is used the actual distribution of the material to the tanks is done by means of the cars above referred to or, as in some cases, by belt distribution. The tanks, 32 ft. \times 9 ft. \times 8 ft., provided with false bottom 9 in.–12 in. from the true bottom, three doors for discharging ripio (refuse), steam coils for heating purposes and connections for transferring liquors and running off finished liquor and washes, are loaded with the crushed material. The size of crushing is varied, according to the hardness of the raw product, from 3 in. for the softest to ¾ in. for the hardest types.

The charge weighs from 60–70 tons. It is now leached in stages, usually 4 or 5 operations being necessary. The first is with the strongest liquor available obtained from the tank immediately behind, and of which the origin will be seen from the description of the complete cycle, and this is carried out at the highest temperature to be obtained, the boiling being continued for a period of from 2–3 hours according to the grade of material under treatment.

At the expiration of this period the boiling liquor, which is now strong enough to send to

the crystallizing tanks, is slowly run off from a point about half way up the tank), the level of the liquor in the tank being maintained by feeding with the next strongest liquor from the tank behind. The "caldo," as it is called, is run off slowly for a period of from 2-3 hours, boiling and feeding being maintained all the time, and the flow is only stopped when the liquor has decreased in strength, due to the weaker feed not being able to be strengthened quickly enough in the boiling tank which is under review.

The feed liquor is intended to displace the caldo running off, but in actual practice it mixes with it and thus limits the efficiency of the operation. When the flow of caldo is stopped, the feed to this tank is stopped and the liquor in this tank is transferred by pump or by levelling action (or both) to the next tank forward which contains fresh caliche, and the preparation of caldo proceeds anew from this fresh caliche. The tank which has now been boiled once is filled up with liquor from the tank behind it (this liquor is the result of the second boiling of the material in this tank) and boiled for a further period during which the new caliche in the tank forward is being boiled for the first time, with the liquor it has received from the tank under description. In this way the caliche is successively leached with four or five liquors in a cycle of operations, the final wash liquor being cold water. The whole operation takes 18 to 20 hours per tank.

The strong liquor (caldo) is run into settling tanks, where it is clarified (sometimes by "time" settling only, sometimes with the aid of flour, dung, etc.) and the clear liquor decanted off into open troughs through which it is conducted to the crystallizing tanks.

These crystallizing tanks are 15 ft. \times 15 ft. \times 2 ft. 6 in.—3 ft. sloping to one side, and an outfit of these tanks is enough to allow of sufficient being filled each day, and occupied for 12-13 days with a two days' supply in reserve. Thus a works filling ten tanks a day will require about 150 tanks for its equipment.

The cooling is done by exposure to the atmosphere and takes 8-11 days, at the expiration of which the plugs, which are fitted in the bottom, are withdrawn, and the mother liquor drained off to open troughs below, which conduct it to the mother liquor stock tank. The crystalline deposit in the tanks is equal to 25-35 lb. nitrate from 1 cub. ft. caldo and for every 1 lb. nitrate deposited as crystal, 0.5 lb. returns to the system as mother liquor. The nitrate after draining contains 8-10% liquor and the crystals are heaped on the drying floors (into which some of the mother liquor drains and is lost) where the heaps are periodically raked over in order to expose more surface, and by atmospheric evaporation and draining, over a period of a month, the crystals are reduced to 2-3% moisture content, after which the lumps are broken down with wooden mallets and the nitrate filled into sacks for entrainment to port.

The factors which prevent this cycle of operations from being as successful as it might be are:—

(1) *The size of lumps of raw material.* This is one cause of inefficient leaching, the liquid only partially permeating the lumps of raw material. This is helped largely by the throwing out of solution, in the more concentrated liquors, of salt, which coats the lumps; and as all successive liquors are saturated with salt, the coating on the lumps becomes an insoluble covering which tends to prevent the liquor getting at the soluble nitrate contained in the lumps. As the final wash is a dilution, with cold water, of the liquor retained by the solid, and not a displacement, and as the material at this stage contains more salt than nitrate (this salt, which has been deposited from previous operations, being more accessible to the water than the nitrate in the lumps), it

follows that all the liquors passing forward from the wash tank and which are used for the lixiviation, in the successive stages forward, must be saturated solutions of salt at their temperature and nitrate content.

The result of this is that dissolution of nitrate takes place, in the further stages, where the liquors are raised in temperature, together with deposition of salt, and the tendency in the high temperature tanks is to deposit salt upon the lumps from which the nitrate is being extracted and thus protect them against the further action of saturated solutions of salt and nitrate.

It is a common thing to be able to pick out of the refuse material (ripio) lumps of quite fresh raw material which have doubtless owed their immunity from attack to the presence of a protecting coating of salt.

(2) *The disruption of the material during boiling.* This causes the insoluble mass to pack closely in the tank, and prevents the free circulation of the liquors in the solid mass, and this is further aggravated by the presence of fines in the raw material.

The raw material after crushing shows by screening analysis a certain proportion of "fines." These fines are due to the breaking down of the softer material during handling and crushing and also to the fines originally brought in with the raw material from the mines (these are produced during the blasting operations necessary to the mining of the material and by the falling in of the soft overburden).

The proportion of fines passing $\frac{1}{4}$ in. mesh varies from 25%-60%, depending on the hardness of the original material and the method employed in loading the carts at the mines (the harder varieties produce less fines in the crushing). Often the "smalls" are shovelled up and thrown into the carts with a lot of fines. Sometimes perforated shovels are used to eliminate the fines. The lumps 30-40 lb. in weight are loaded into the carts by hand.

The presence of these "fines" in the boiling tanks is very prejudicial to successful lixiviation as they interfere with the proper circulation of the liquors.

Furthermore the space between the true bottom of the tank and the perforated false bottom (crinoline), 9 in.-12 in., becomes filled with part of these fines which remain wet with a very strong nitrate solution mixed with nitrate crystals, for this space is the coolest part of the tank. Often enough the total loss of nitrate from this source alone accounts for 10% of the total production, or 4-5% of the total nitrate in the original material. This fine waste, locally known as "borra" has been the object of many experiments in order to reduce the high nitrate content, but, as washing the nitrate out only produces weaker liquors which cannot always be successfully introduced into the cycle, and filtration has only recently been tried, the borra is almost invariably thrown away without treatment.

(3) The presence of clay and other amorphous matter, oxides of iron, aluminium, etc., causes the otherwise fairly easily drained material, e.g., stones, gravel, and sand, to become much more "spongy" and augments its power to retain liquors on draining, with the result that when it is necessary to drain off stronger liquors previous to treatment with weaker ones for the purpose of lixiviation, a greater percentage of the stronger liquor remains than otherwise would do in the absence of such amorphous matter. The effect of this is the limitation of the amount of nitrate solution passed forward in the system, with a corresponding decrease in the efficiency of the process.

Furthermore the amount of liquor used in the cycle is strictly limited to the amount of nitrate to be dissolved, so as to be able to run off the

greatest quantity of sufficiently concentrated liquor from the first tank in the cycle, and hence the above inefficiencies cannot be rectified by the use of more wash water. The residues must of necessity be thrown out wetter and richer.

These factors not only make the cycle of operations as it is used to-day inefficient, but prevent this particular method being used with success to treat finely crushed material.

It will be readily understood that the process becomes highly inefficient when the raw material contains a high proportion of this insoluble matter, which, as refuse, contains not only nitrate still untouched in the lumps but 30-35% of liquor content, which liquor, due to bad draining and inefficient displacement by subsequent washes, is a fairly strong solution of nitrate and salt.

When very high grade material was used these features came into little or no prominence owing to the comparatively small proportion of insoluble matter in the raw material.

Even when the most primitive form of the process was in use and the dumps were discarded with 20-30% nitrate and the fines with 40-50%, the quantities of both dumps and borras were so small as still to leave the process efficient enough for the objects aimed at in those days, the losses being about 30-35% of the total nitrate in the caliche originally.

Now, however, with raw material containing 17 to 20% nitrate of soda or less and 20 to 25% salt and 50 to 60% of insoluble matter or more, these features assume considerable importance and, even with all the mechanical improvements and labour saving devices which are used to-day, there is a limit to the poverty of the material which can be successfully exploited by the process in use, the efficiency of which is still consistently so poor as to demand alteration and improvement.

TABLE 3.

Increase of exports of nitrate of soda from Chile, 1900 to 1915.

In fact 45-55% efficiency is all that can be expected, and although many works show a higher efficiency than the above figure in their returns it is very doubtful if accurate weights and samplings were taken as the bases of estimation, whether 50% efficiency was ever exceeded.

An average oficina's working may be expressed as follows:—

Weight raw material	unit	
Nitrate content 17%	1000 tons	
Nitrate produced (50% yield)	170	
Nitrate in refuse:—		85 tons 50%
Ripio at 3.4%		34 „ 20%
Borra		17 „ 10%
Unaccounted losses		34 „ 20%
		170 tons 100%

Table 3 shows the increase in export of nitrate of soda from 1900-1915.

Improvements in the method of lixiviation of the raw material.

As in old established industries, there is in Chile a distinct aversion from radical alteration and most of the newer schemes tried have had to be put forward as palliatives to the old process.

Unfortunately there have been up to the last two or three years no successes striking enough to draw attention to in detail, but projects for the economy of fuel, steam, labour and so on, have received attention and trial.

Forced circulation in the boiling tanks has been exhaustively tried without success; filtration through a medium placed between the true and false bottom of the tanks, alterations in shapes and sizes of tanks, details of manipulation, local changes in methods of introducing liquors, washes, etc., in fact all types of unorganised research, mostly devised and carried out by practical men without much scientific guidance, have been tried and discarded.

Methods of evaporation have come in for a share of experiment, the application of evaporators being based on the idea that by use of more water in the system and not running off fully concentrated liquors in the first boiling (concentrating up to crystallising strength in the evaporators subsequently) an additional extraction of nitrate from the raw material would take place.

This means, in effect, the use of weaker extracting liquors throughout the cycle. There is no doubt that evaporators have justified themselves to some extent, where they have been used. As, however, the expense of evaporation has been found to limit the application in the particular way desired, and the advantages are not always proportionate, evaporators have not been universally adopted.

Furthermore, weaker liquors produced by the old system must contain more salt than the previously stronger ones did. This salt is precipitated in the evaporators, entailing, in the subsequent freeing of the liquor from crystals of salt, by settling and decantation, a considerable loss of nitrate out of the caldo. An examination of the features outlined previously as defects in the present lixiviation system will prove that the addition of more water to the system can only have a partial influence, viz., that of weakening the liquors adhering to the solid refuse. The nitrate in the solid itself will not to any great extent be further extracted owing to the presence of the salt acting as a protector.

In effect the fringes of the problem only have been attacked, and great credit is due to those who endeavoured to attack them, hampered as they were by many circumstances both local and general. As stated previously, there was a great aversion from altering radically the type of plant in use then and to-day, an aversion which was justified only by the absence of results from co-ordinated experiment and research.

If the working of the lixiviation process had received thorough examination, and its defects had been properly located, a huge number of the trials and experiments would never have been carried out.

For example, efforts were made to crush the material finer, in order to bring the raw material in closer and more intimate contact with the liquors. As, however, the same lixiviation method was used it is obvious that this was foredoomed to failure, as indeed it subsequently turned out to be.

Cold water extraction combined with evaporation was also tried (Mason's system), but the methods of evaporation used did not prove satisfactory, neither did the lixiviation process, which was carried on in the same tanks as are in use to-day, the raw material being crushed slightly smaller.

An attempt was made to use the boiling tanks (this time egg-shaped and closed) in such a way that the boiled off steam from the strongest tank effected the preliminary heating in the next. The strong tank was worked partially under vacuum, not for boiling purposes, but for drawing through the mass the air used for agitating the contents of the tanks in order to procure the best mixing. This process, invented by Nordenlycht, was tried exhaustively but eventually failed.

Methods have been tried in which the principle (System Grillo and Perrori) was to work the tanks to weaker liquors and evaporate; the boiled off steam from the evaporators was used to provide the heat in the lixiviation plant (Shanks type), being introduced through perforated coils beneath the erioline plates or false bottom.

Some of these improvements indeed have given slightly better results, justifying themselves both by cost of installation and by final cost of production, but most have been too costly to install, and too complex and costly to work. All, however, have been palliatives and hence their utility has diminished with the ley of the raw material to be treated.

Within the last few years a revival of experimenting has taken place, with the result that there is ample opportunity for a new co-ordination of effort, which is now assisted by the fact that the old bias against a complete modification of the process and methods has weakened. In fact several processes are now available for test in actual practice, having been exhaustively worked out, and the experimenters are busy with hopes of success.

They aim at a complete or partial change in the process and plant, and we will pass on to as detailed a study of the two most prominent as is possible with the information at present available publicly, assisted by communications and reports from experimenters.

The year 1912 witnessed the initiation of two processes which are now undergoing commercial development in Chile and which merit detailed description, namely, the Butters process and the Gibbs process.

The following details of the Butters process are taken from a description thereof given by Mr. J. T. Humberstone at the Mining Congress held in Santiago de Chile in April, 1916, supplemented by reports and descriptions received from private sources.

The Butters process was developed by the Butters Vacuum Filter Co. assisted by Mr. J. T. Humberstone in Oficina Agua Santa, Tarapaca, Chile.

It is based on the use of the Butters vacuum filter as the means by which the nitrate and salt solutions are removed from the insoluble matter. It is proposed to reduce the whole of the raw material to sufficient fineness, by grinding in ball mills with hot weak nitrate solution, that it will be amenable to treatment in the standard Butters filter. After grinding, the pulp is further heated by steam coils, in order to cause solution of the nitrate, air agitation going on the while.

In the Agua Santa works the fines (11% nitrate content) are mixed with liquor (150 grms. nitrate per litre) in the proportion of three of solid to one of liquid. The hot pulp is then filtered in the Butters vacuum filter and a certain proportion of liquor is extracted in this way. This liquor is of varying strength depending on the amount of weak liquor (and strength thereof) which is used for the extraction and the proportion and richness of the raw material used with it.

The inventors claim that it is possible to prepare a liquor, by this means, which can be sent direct to the crystallising tanks, but so far this claim has not been substantiated in practice. In fact the inventors state that it is preferable to work for the preparation of a liquor containing about 450 grms. of nitrate of soda per litre, which would

GIBBS PROCESS—DIAGRAM OF LIXIVIATION SYSTEM.

show a density of about 75° Tw. and temperature of about 80° C. Such a liquor would have to be concentrated in evaporators (a liquor generally considered good enough to go to the crystallisers will contain about 750 grms. per litre of nitrate of soda and 120 grms. per litre of salt, and have a density of 104° Tw. at 102° C.), separated from the insoluble salt, and crystallised in order to regain the nitrate, but the Butters process has not considered the necessity of evaporators so far. They prefer to use the process as an auxiliary to the existing system. The cakes are subsequently washed twice with weakening liquors: the washing is claimed to be by displacement only and the final wash is done with salt water (saturated brine) which leaves the cakes with about $\frac{1}{2}$ % nitrate of soda. The cakes are then discharged. The different liquors obtained from each successive displacement wash are used in the next round, the whole forming a cycle of operations, at one end of which the strong liquor is removed, while at the other end the cold brine "displacement" wash takes place.

As it is being used at present in Oficina Agua Santa, the Butters process acts as an auxiliary process to the main Shanks Maquina, and the results claimed so far are sufficiently good to restrict the working of the process to these lines.

The process, which has now worked there for nearly a year, consists in screening the whole of the crushed product in order to remove 20% of it as fines passing a 6 mm. mesh. These fines are treated by the Butters process as described above.

The coarser material alone is treated in the boiling tanks, as formerly, and the liquors obtained from the Butters process are introduced into the cycle of operations in the Shanks system, the whole process being assisted by evaporators previously installed in the works.

By the combination of Shanks process, Butters fines treatment, and evaporators, material of 14.5% nitrate content is worked successfully with an efficiency of 64% as against an efficiency previously obtained by the Shanks process *plus* evaporators alone of about 50%. Working costs appear to be fairly high, but in view of the increased yield of nitrate obtained from the same amount of raw material the combination of processes must be admitted to have met with success. As to what measure of this success is due to the Butters system alone it is difficult to state, as it is claimed that by the mere elimination of fines alone the lixiviation in the Shanks system is so very considerably improved as to increase the yield therefrom from 50% to 61%.

Without the use of evaporators it is doubtful whether any such improvement would be shown, and it is more doubtful still whether the strengthening up of the liquors produced by the auxiliary process by passing them over the coarse material in the Shanks system, is a satisfactory way of using these liquors, without recourse to evaporation.

But it is certain that there is a limit to the amount of such liquor which could be strengthened up in this way, without evaporation. If it is assumed that 75% of the total material is fine and the other 25% coarse, the fines will contain 75% of the total nitrate, of which 90% will be extracted and made into weak liquor: the coarse will contain 25% of the total nitrate only, of which but 65% at the outside can be extracted in the Shanks Maquina. This means that there will not be enough nitrate available in the coarse to bring the liquors from the fines to crystallising strength.

As the process stands at present it is claimed, (1) A 90-95% extraction of nitrate from raw materials as low as 11% in average and the ability to produce liquors which can be directly crystallised for their nitrate of soda content. (2) That this can be carried out at low labour and fuel cost. As we have pointed out, it has not so far

been worked in this way, but only as an auxiliary process to the Shanks system combined with evaporators, in which combination its actual success, cost of operation particularly, is obscured by other factors.

The process is still in course of trial and doubtless will be improved in many ways and perhaps, eventually, successfully applied to certain of the particular needs of the industry of the future.

The Gibbs process.

Early in 1912, Messrs. Gibbs and Co. of Valparaiso despatched their engineer and chemist, the writers of this paper, on a tour of investigation through the U.S.A., France, and Germany, in order to gather as much information as was possible on methods used in other industries, so as to be able to develop the Chilean nitrate industry on more modern lines.

This resulted in the initiation of a process, on completely new lines, consisting of a new method of lixiviation and a process of evaporation which combined the regaining of the nitrate direct together with the separation of the sodium chloride. The details of the process were worked out in England, the theoretical part at the Manchester School of Technology, and later at the experimental laboratories of Messrs. G. T. Holloway and Co., and the practical part at the latter laboratories and near Mitcham, where an evaporation plant was erected on the principle worked out in conjunction with the Kestner Evaporator and Engineering Co., Ltd., of London. The results were completely satisfactory and a demonstration was given in July, 1914, before the representatives of the nitrate industry and the Chilean Ambassador and his suite.

The Gibbs process aims at the treatment of the raw material as two separate sections in the problem. (1) Lixiviation of raw material; (2) Concentration of liquors from 1; and No. 2 may be subdivided into (2a) Separation of salt contained in the liquors from 1; (2b) Separation of nitrate of soda.

(1) *Lixiviation of raw material.* The Gibbs treatment of raw material is based on the observation that in typical caliches, both of high and low grade, the soluble material is the binding agent by means of which a conglomerate of insolubles is held together.

This insoluble material consists of stones and sands together with finer matter such as clay, oxides of aluminium and iron, etc., which may be considered to be slime formers. (It is these slimes which prevent the free lixiviation of the mass and complete removal of liquors therefrom, and the removal of these slimes is the prime object of the Gibbs lixiviation scheme.) The stones and particles of sand, etc., are quite in their native state and are free from soluble matter with the exception of what is crystallised round them. If, in the laboratory, the raw nitrate-bearing material is treated without any grinding or breaking at all, with dissolving agents (hot water) in such a way as to wash out all of the soluble contents, the insoluble remainder, when ground to an almost impalpable state, will show practically no further trace of soluble matter. The results of the washing will be to produce a stoney, sandy mass which is quite valueless for nitrate content.

A reference to the screening tests, Table B, on two extreme caliches will show what occurs after complete lixiviation.

It is on this principle of separation and removal of slimes during lixiviation that the Gibbs system of lixiviation is based and the objective is reached in practice in the following way. The raw material is crushed as usual to about 2 in.-3 in. and fed into a mill together with nitrate solution at about 50° C.

TABLE B.

Screen test and analysis of caliches.

Mesh 1 mm.	% of Insolubles.	A.	B.	Analysis.	A.	B.
Plus 5	Sands and stones.	21.75	45.30	Sodium nitrate	24.93	9.66
" 8	"	8.39	9.10	" chloride	25.30	9.87
" 10	"	3.06	4.80	" sulphate	2.20	8.27
" 20	"	10.71	11.70	Max. chloride	7.27	—
" 30	"	5.34	4.40	Calcium chloride	3.37	—
" 40	"	5.72	4.40	" sulphate	—	3.97
" 80	"	12.21	5.60	Other solubles	10.73	1.00
" 100	"	6.10	2.20	Total solubles	73.80	32.77
Minus 100	Sands	13.74	6.60	Insolubles	26.20	67.23
" 100	Slimes	12.98	5.90	Total	100%	100%

This mill, worked without balls or pebbles, acts purely as a disintegrating mill, in which the raw material is reduced to its ultimate particles with the minimum of grinding or slining action.

The pulp is passed continuously from the mill to a series of classifiers in which the lixiviation action takes place in counter-current.

Assuming four classifiers in the series, water is fed into No. 4 where it washes the already thrice washed insoluble matter and the wash from this is passed forward to No. 3 which it washes and in turn is passed to No. 2 and finally to No. 1. The insoluble matter passes from No. 1 to No. 2 and onward to No. 4 whence it is discharged.

The object of the classification is two-fold. In the first case the classification is for the separation of the slime-forming fines, together with a proportion of fine sand, in effect the washing off from the bulk of the raw material that portion of it which is about -80 mesh. In the second case, assisted by a rise of temperature to whatever is decided as convenient, solution of nitrate is brought about by intimate contact between wash liquors and particles of raw material.

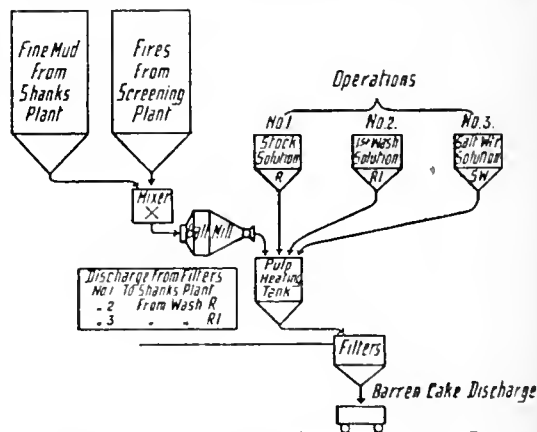

The liquor coming from classifier No. 1 contains then all the -80 insolubles while the +80, together with adherent solution (from which it is drained as much as possible on its passage to No. 2 classifier) and undissolved nitrate, passes to No. 2 where it meets the weaker wash from No. 3. Slight classification may take place here, but essentially the function of this and the following classifiers is to bring the solid particles into intimate contact with the weaker liquors. The action takes place in four stages and the final insolubles, passing out of No. 4 stage or classifier, are in the form of clean sand, gravel, stones, etc., which do not contain, locked up in crevices in the particles, any more than $\frac{1}{4}$ % nitrate of soda. As the mass can be easily washed and drained the loss of nitrate in this part ought to be little more than that quantity. Having extracted the nitrate and disposed of the bulk of the insoluble matter, the liquor obtained from No. 1 is a saturated solution of nitrate and salt together with the other soluble salts and containing the -80 insoluble *viz.*, fine sands and slimes.

It will be noted that the classification aimed at is not the fine classification desired in most mining propositions, and the principal object, that of removing from the insolubles the fine portion, permits of the easy and cheap washing and disposal of the rest of the bulk. As will be seen from the screen tests shown (taking the classification as separating the + and -80 mesh) the amount separated as -80 will be in the case A 32.82% of the insolubles or 8.6% of the total raw material, and in case B 14.7% and 9.88% respectively, and these quantities have to be filtered out of the liquor obtained from No. 1 classifier. This filtration is carried out by means of the Oliver

continuous vacuum filter, which is a revolving drum of which about one-third of the circumference at a time is dipping under the liquor to be filtered.

The drum is divided into segments which in turn are connected to vacuum and compressed air and the operation is mechanically controlled by means of a disc valve, the cake being sucked on by vacuum while that part is dipping into the liquor (kept agitated), sucked dry for part of the time it is out of the liquor, spray washed and dried also under vacuum, and finally scraped off after being loosened by compressed air.

DIAGRAM OF FILTER TREATMENT OF FINES
AUXILIARY TO MAIN (SHANKS) PLANT—BUTTERS
SYSTEM.

The net result of the operations is that about 10% of the raw material is treated by the more expensive filtration process while the rest of the insolubles, case A 17.6% of the raw material, case B 57.32% of the raw material, is washed quite free from its soluble nitrate contents and discharged without any filtration or expensive treatment. The advantage in the case of low grade material is obviously enormous.

The process has been designed to obtain a liquor containing about 450 grms. of nitrate of soda per litre and about 200 grms. of salt, with about 50 or 60 grms. of other soluble salts, as calcium and magnesium sulphate, chloride, and nitrate, sodium sulphate, etc.

By increasing the temperature of operation a stronger liquor may be obtained, but this increase in strength by rise of temperature is subject to economic limitations which it is intended shall be studied on the large scale on the spot.

The actual experiments on the large scale show

the losses to be approximately $\frac{1}{2}\%$ nitrate on the +80 mesh and 2% nitrate on the -80 mesh, or out of 1000 tons caliche A (24.93%):

262 tons insolubles would contain 86 tons slimes	
at 2%	=1.72 tons
262 tons insolubles would contain 176 tons coarse	
at $\frac{1}{2}\%$	=0.88 ..
	2.60 ..

Out of a total of 249.3 tons nitrate of soda hence 246.7 tons is recovered or 98.9% yield.

In case B—

1000 tons of material 9.65% nitrate:—	
98.8 tons slimes at 2% nitrate	=1.976
573.2 tons coarse at $\frac{1}{2}\%$ nitrate	=2.866

4.842 tons nitrate.

Out of a total content of 96.6 tons nitrate of soda the yield is 91.758 tons or 95%.

Evaporation.

As mentioned above, the standard liquor aimed at in the lixiviation system above outlined contains nitrate of soda 450 grms. per litre, salt 200 grms., other solubles 50 grms., water 650 grms.; total, 1350 grms. per litre.

The evaporation system is divided into two sections, one aiming at the almost complete separation and recovery of the salt, while the other recovers the nitrate of soda direct in the form of crystals.

In the first part the evaporation is carried out as a double effect. In the lower temperature effect the evaporation is done under vacuum at about 80° C. and the liquor from this goes to the second, the higher temperature effect, for evaporation at about 124° C. under normal atmospheric pressure.

At this temperature practically the whole of the salt is rendered insoluble and the plant, a modification of the well-known Kestner evaporator, is arranged so as to ensure the transference of the desalted liquor without loss of temperature (and consequently nitrate of soda) and completely free from suspended salt, to the nitrate crystallizer, which is a vacuum effect without calandrias.

KESTNER PATENT
SALTING TYPE EVAPORATOR

Here by cooling and self-evaporation under vacuum the nitrate crystallises immediately and is removed from the coded bottom by a screw and dried in hydro-extractors. The apparatus is shown in accompanying figure and works approximately as follows:—Effect No. 1, which is

worked under a suitable vacuum, causes the deposition of about 50% of the total salt contents of the liquor. This salt is removed by a mechanical screw and sucked dry and washed in a vacuum filter. The liquor from No. 1 passes to No. 2 where the maximum temperature desired is reached. This brings about the completion of the desalting and the liquor, now boiling at or about 124° C., is transferred to No. 3, a vacuum effect without calandrias where the nitrate is deposited.

The salt from No. 2 effect is periodically removed by means of the specially designed filter box, which permits of the salt being washed after draining and disposed of with the minimum loss of nitrate of soda. The steam produced in effect No. 2 is used for procuring the evaporation in No. 1 and all surplus steam is diverted to a preheater or to the lixiviation plant.

The advantages claimed by the Gibbs process are:—1. Cheapness of installation. 2. Ability to treat cheaply and effectively low ley caliches with an efficiency of 90% extraction over all. 3. Ease of control of process. 4. Direct crystallisation of nitrate, ensuring ability to trace losses and remove their causes almost at once. 5. Greater control over the working of the nitrate deposits.

Advantage No. 5 should give an incentive to the development of the mining of nitrate of soda. Many causes, chief among which is the necessity for hand selection of the material used to-day, have conspired to prevent the development of the use of mechanical drills and shovels in the Chilean nitrate fields.

It is to be expected that with the advent of the newer processes no longer necessitating the specially hand selected material, these causes will automatically disappear and the more rational mining come into its own.

The mother liquor from the hydro-extractor is periodically examined for lime and magnesia content, and treated for the conversion of these into sodium salts when necessary, separated from the insoluble magnesia and lime, and returned to the system, being introduced into either the high or low temperature effect according to circumstances. Periodically the accumulated iodine salts will be examined and the iodine extracted by precipitation in the usual way.

The cost of a complete installation of the Gibbs process is estimated to be about one half that of the present type of plant, and it is expected to be able to treat material of as low a ley as 10% with 90% efficiency, at a cost reduced in a marked degree. There can be no comparison of costs when working with 10% material with the Gibbs process because the present type of plant cannot deal with it at all.

The first Gibbs plant is now being constructed for the Fortuna Nitrate Co. for their Oficina Celia. Antofagasta, Chile, and it is expected to commence actual work within the next 9 months.

Future of the nitrate industry in Chile.

Without endeavouring to enter into the question of the prospects of Chile nitrate as regards the competition from the artificial nitrate industry or to attempt to forecast the possible effect of the war or future consumption of both artificial and natural nitrate, it may be confidently anticipated that the Chile nitrate industry has a rosy future before it.

In spite of the numerous statements issued to the effect that the natural deposits were rapidly approaching exhaustion it may be confidently asserted that such is by no means the case.

Although the year 1921 is mentioned as the crucial year in which Chile as a serious producer of nitrates will be *hors de combat*, there is as yet no sign of such a state of affairs arising. On the contrary, the quantity of available nitrate, estimated on the present basis of working and

based on the official Chilean Government reports, is particularly reassuring.

The idea of the rapid exhaustion of the Chilean deposits has been definitely refuted in a statement issued by the Chilean Nitrate Committee, under the auspices of the Chilean Embassy. This statement was issued in November, 1913, in response to the extensive advertisements issued by the Nitrogen Products Co., in their appeals to the public for support, and which emphasised the importance of their undertakings on the grounds (among others) that according to Sir W. Crookes and others, the Chilean deposits were due for exhaustion in 1921.

According to the official Chilean statement, which is reproduced here by permission of the Chilean Nitrate Committee, these opinions fall far short of the reality.

According to the latest official report presented to the Chilean Government by Mr. Francisco J. Castillo, the Inspector-General of the Nitrate Deposits, the zone of nitrate bearing grounds comprises 200,000 square kilometres, of which so far only 5811 square kilometres, that is to say, less than 3%, is examined, and their contents ascertained by excavations and test holes. These 5811 square kilometres belong to the existing companies, private firms, and in part are still in the hands of the Chilean Government.

The calculated contents of these 5811 square kilometres were 290,300,000 tons of nitrate of soda, of which up to the present 15,000,000 tons has been extracted and exported, leaving in the examined part of the area, 245,300,000 tons of nitrate of soda equal, at the present rate of production, to a supply for a further 100 years.

As the unexplored part is some 34 times larger than the explored grounds, it is safe to estimate that it contains altogether at least an equal quantity of nitrate of soda, and consequently the nitrate zone in Chile can certainly provide nitrate of soda for another 200 years at the present rate of production.

The quantity of nitrate of soda remaining in the examined grounds is sub-divided as follows:—

Province of Tarapaca	35,000,000 tons.
Tocopilla District	28,000,000 ..
Antofagasta (Central)	32,000,000 ..
Antofagasta (Aguas Blancas District)	49,000,000 ..
Taltal	95,000,000 ..
Chanaral and Copiapo	8,300,000 ..
Total	245,300,000 tons.

The Inspector-General of Nitrate Grounds, in his report to the Chilean Government, has arrived at these figures in the following way. In these examined grounds no raw material containing less than 11% of nitrate of soda has been taken into consideration, nor grounds where the thickness of the layer of raw material was less than one foot, except in the case of raw material of at least 25% of nitrate of soda, when the thickness of eight inches and above has been included. The superficial area of each portion of ground examined has been divided by the total number of test holes made, in order to arrive at the area applicable to each test hole, and this consequently determines the total nitrate-bearing area. From the theoretical quantity of pure nitrate of soda resulting from the above operations a reduction of 40% has been made in order to provide for losses in extraction, manufacture, errors of calculation, etc.

Of raw material of a lower grade vast quantities remain, which have been excluded from these calculations because they cannot be profitably extracted under the present system of work: but as improvements are being constantly made, there is every reason to assume that even this low grade material will be worked when the richer qualities are exhausted.

These statements therefore conclusively show that there is no fear of the Chilean nitrate deposits being exhausted for 200 years.

In 1913 the duration was estimated at 200 years on the normal working and normal efficiency of the plants. It will be obvious that with the present type of material the new process when installed will give an effective yield of about 85% in place of 50%, i.e., the quantity of raw material previously available for 50 years' work will become available for 85 years' work. This makes 200 years equal to 340 years.

In addition, no material of less than 11% is included in the above estimate, so that if the new processes can effectively deal with an average of 10% a vast field is opened for further exploitation which would probably treble the available duration of the grounds, and further with the ability to treat 10% material many of the huge dump tips will become available for use again very profitably.

It is from this point of view that the future of the Chilean nitrate industry is very bright.

Its development has only just been started and no doubt many fresh workers, both chemical and engineering, will be attracted to the spot to assist in bringing its development to a successful issue. With the manufacturers alive to the possibilities of the new processes and possessing the determination to try them thoroughly, and with the practically limitless quantities of raw material lying there, the future need fear nothing.

It is interesting to note, in this regard the question of iodine. Iodine is a very important by-product of this industry, the raw material often containing up to 1 part of sodium iodate in 100 parts. Up to the present only a small proportion of the available iodine is extracted from the prime product, the remainder being allowed to be lost in the dumps. The mother liquors which are returned to the lixiviating system are periodically treated for the iodine they contain by precipitating the element with sodium bisulphate. The methods employed are exceedingly crude. The work is carried on intermittently and during each period of working, sufficient iodine is extracted to last as stock, for the particular oficina, for years. No further extraction of iodine is done until such time as it becomes necessary to replenish the stock.

In the newer schemes it will undoubtedly become necessary to extract the iodine completely and constantly, thereby necessitating the modernising of the methods employed. At the same time the quantities available will become much larger and doubtless much work will be done at this end of the world in finding new outlets for so useful a product.

The Chilean nitrate industry would probably be very interested in helping to discover the uses for the greater production.

The authors are indebted to Mr. G. F. Morrison of Iquique for permission to use the analyses given, to Sir R. Harvey for his information of the earlier stages of the industry, to Messrs. G. T. Holloway for the screen analyses, and to the Chilean Nitrate Committee for information supplied.

DISCUSSION.

The CHAIRMAN, in inviting discussion, said that it was a remarkable fact that the nitrate industry had only recently commenced to use multiple effect vacuum evaporators. The system of evaporating in open pans was well known to entail an enormous waste of fuel.

Mr. W. G. MANN said that there were in connection with every "Oficina" some hundreds of open cooling tanks which ought to offer opportunities for very reliable data on the subject of atmospheric cooling and crystallising. In connection with the new system of nitrate production the problem of quick and efficient cooling and crystallising was exceedingly important, and

when he was working in conjunction with the authors he had been unable to find any really reliable data on the subject in the technical literature available. He suggested that some of the fundamental problems of chemical engineering might be dealt with by a Committee of the Society and thoroughly investigated in the same way that certain engineering problems were exhaustively examined by the mechanical and civil engineers.

In answer to the expressions of surprise made by the Chairman and others that multiple effect evaporators had not already been at work on caliche solutions, Mr. Mann drew attention to the very difficult nature of the caliche liquor from the point of view of the evaporator problem. The table giving typical analyses of caliches showed that a number of substances are present in addition to the sodium nitrate and chloride, which, although present in relatively small amounts, had a very great effect in hastening scale formation and incrustation. The trouble was further aggravated by the presence of fine dust from the crushing mills. The problem had been solved by the introduction of an evaporator which allowed for rapid circulation in the heating tubes and also the isolation and cleaning of the heating units by means of the multi-calandria arrangement attached to a central separator.

Mr. E. V. EVANS said that certain important apparatus now used in the chemical industry had originated from saltpetre recovery processes. One in particular had been communicated to him which served a very useful purpose in this country. It was often necessary to design a cooling system for hot saturated solutions of a crystallisable product, which, on cooling to normal temperatures set almost solid. The obsolete method of effecting such an operation was to place the liquor in crystallising vats, and the authors had shown that in the older installations in Chile each vat charge required about ten days to cool, and in consequence, a considerable ground space was covered by this portion of the process. The means suggested to overcome this difficulty was to employ a high speed centrifugal pump for pumping the hot liquor through a long coil of iron pipe, which was cooled externally by water. In the normal way this pipe would have become blocked by crystals, but it was found that if the speed of the centrifugal pump were sufficiently high the tendency for the crystals formed within the liquor to adhere to the pipe, was overcome by the high velocity of flow. Thus with each crystallisable liquid it became necessary to determine firstly, the rate of flow that would satisfy the above conditions, and secondly, the length of cooling pipe that would be required to bring the liquor to the required temperature. He had no knowledge of the value of this appliance when dealing with nitrate of soda solutions, but felt that the combination of the triple effect Kestner evaporator and the above-described cooling device should find frequent application in the chemical industry.

Dr. R. SELIGMAN drew attention to one point in the paper in which it was stated that crude oil was easily available for fuel purposes on the caliche fields, but presumed that what was meant was that crude oil was more readily available than coal and not that oil of local occurrence was used. He further asked whether on the caliche fields water was not extremely scarce and consequently valuable. If that were so, as he believed to be the case, it seemed all the more remarkable that methods of evaporation and drying were used which seemed especially designed to waste water rather than to conserve it. That should be an added incentive to the development of modern methods of evaporation.

Sir FREDERICK NATHAN said he could confirm the presence of iodine in Chile saltpetre, and he

had often seen crystals of iodine subliming over with the nitric acid produced from Chile saltpetre.

Mr. WALTER F. REID said that the iodine was very much required in the manufacture of organic chemicals. He asked if the question of evaporating in open tanks by means of the sun had ever been dealt with in Chile.

Mr. J. W. MACDONALD thought that a diffusion process similar to that used in the extraction of sugar from beet might probably replace the Gibbs system. Less water would be required.

Mr. T. D. MORSON said that the present price of iodine was altogether an artificial one, and he agreed that it should be recovered.

Dr. MESSEL enquired how much iodine (by weight) was contained in a ton of caliche.

Mr. REAVELL, replying to the discussion, said that the first point referred to crystallising out the nitrate solutions in large open tanks. The suggestion was made that instead of using the enormous number of tanks that were necessary in an oficina, the liquid should be pumped at high speed through coils, cooled externally by means of water flowing over them. It had to be borne in mind that, whilst it was possible to use such a system with some highly concentrated solutions, it had been found very difficult to pass hot nitrate solutions through pipes as, on cooling, the crystals fell out so rapidly that such a system as mentioned had never been found to be satisfactory. Similar expedients had been tried, but without success. From information at present available he understood that the iodine from Chile was practically in the hands of a "ring" who undertook only to produce a certain amount of iodine so as to keep up the price, the rest being thrown away. There was no reason why enormous quantities of iodine should not come from "caliche" as the quantity present in the "caliche" in accordance with the above tables, in the form of iodate of soda, varied from 0.01% to 0.15%. This iodine could easily be recovered. It had to be admitted that the methods adopted in the industry were antiquated, particularly on the chemical side, and that the only improvements for many years had been in the mechanical side in the way of electric driving and improved methods of handling raw material, etc.

Informal Meeting held at the Birkbeck Café, Holborn, W.C., on Tuesday, December 19th, 1916.

MR. ARTHUR R. LING IN THE CHAIR.

A Discussion was opened by the Chairman on—

THE WORK OF THE SECTION.

The CHAIRMAN, explaining how the idea of holding the meeting had arisen, said that it had come to the knowledge of the Committee that some of the younger members held the view that they were not taking a sufficiently active part in the business of the Section. For example, that the discussions were to a great extent monopolised by what he would term front bench members. The Committee were well aware that the younger members of the Section did not come forward in discussing the papers so freely as they ought, and if the majority of those taking part in the discussions were front bench members, that was because the younger members were shy, and the main object of informal meetings was to bring them out. It was thought that informal meetings should be held in some other place than Burlington House, in a place where there were no front benches, where all the members could sit round various tables, partake of light refreshments, and exchange seats during the discussion. In that way they would get to know one another and foregather.

There was a strong feeling among members, especially those in the provinces, in favour of the reporting of proceedings of the meetings other than papers and discussions, so that the different sections should become better acquainted with what each was doing. To some extent such proceedings were reported at the present time in the trade journals. But it was strongly urged, and he thought quite reasonably, that their own Journal was the place where they ought to find a record of their doings.

It had been the object of the Committee of the Section to get a series of papers from different authorities on certain branches of applied chemistry, and as would be seen in the Journal a most interesting programme had been arranged.

He believed that the question of the Federation of Chemical Societies, as suggested by Professor Armstrong in a paper read before their section last year (this J., 1916, 35, 502) would be promoted to a great extent by holding meetings such as the present one. There was no doubt that the time had come when chemistry in this country must make its voice heard as medicine has done. It was a remarkable fact that when the Government or any corporate body wished for any assistance in chemistry, they did not approach the Society of Chemical Industry, which it appeared to him was the proper body to deal with such matters. He might cite the fact that at the outbreak of war, the Government approached the Royal Society, who formed various Committees to deal with chemical questions. If the various chemical societies had been federated, then such questions would have been submitted to them. It seemed to him that it was just as logical for the Government to go to the Royal Society on a medical question as it was for them to go to that Society on a chemical question. The reason the medical profession had not been excluded was that they had made themselves known, and made themselves strong by federating.

Even before federation took place, it seemed to him that some steps ought to be taken to get a habitation in London. This project had been suggested many times previously, and some had held the view that it would meet with a certain amount of disapproval from the Provinces. That he could assure them was not the case. The Provincial member who was in the habit of coming to London desired some sort of Chemical Club in which he could meet his friends, even more than did the London member.

In 1898 when he became Secretary of the London Section the membership was about one thousand, and now it was slightly over that number, so that in those eighteen years there had been no substantial increase. Surely it should have been otherwise. He urged them to use their endeavours to induce their friends to join the Section.

Mr. A. H. DEWAR said that they wanted the Society to be, not only an instrument for the development of chemical industry, but a real live organism cultivated on enthusiasm. They should be a real live branch of chemical industry, and they therefore welcomed this meeting as an indication of a move in this direction and especially the invitation to young members. It must be remembered that they would be the future mainstay of the Society, and anything that would lure them from their shyness was to be commended. As to the work of this real live Section, endeavour should be made to have papers of a more technical nature. They had had many good papers, but most of them had been more suited for the Chemical Society than the Society of Chemical Industry. To get such papers difficulties would have to be overcome. Some directors were afraid to let their chemists speak—every opportunity should be taken to let such men see that intercourse between chemists was conducive to their companies'

advantage. Wise use must be made of the privileges thus obtained. The chemical industry must learn that the days of "splendid isolation" were past, and what now was needed was "splendid co-operation and collaboration." The work of the Society must be carried on, in a fraternal spirit, on these lines if it was to justify its claim to speak for chemical industry.

Dr. S. MALL alluded to the difficulty felt by a manufacturer who was rather ignorant of chemistry. He found few papers which were sufficiently elementary and general to interest him and hoped it would be possible to introduce more of such into the Journal. He called attention to the amount of space taken up by abstracts of highly technical matters. Finally he hoped the Section would be able to arrange visits to works.

Mr. W. J. COWAN said that in his opinion there were many matters that might be altered or improved with advantage to the Society. The establishing of a club for chemists and others allied to chemical industry and chemical engineering in some central position was, he believed, a long-felt want, and if launched would, he ventured to predict, be the means of creating a closer *esprit de corps* than at present existed among the members of the Society.

Mr. H. E. COLEY suggested the immediate formation of a small Committee, consisting preferably of members not at present on the Executive, to draw up a scheme for the formation of a Chemical Club in connection with the Society. It was absolutely necessary if the chemical industry of the country was to be welded into anything like a powerful body, that some better means should be provided to enable members to meet one another and exchange views. The impression in the mind of the ordinary member of the Society was that nothing had been done to make for unity, and that something ought to be done quickly.

Dr. H. V. A. BRISCOE suggested that an immediate step might be taken to arrange discussions on subjects chosen so as to provide opportunity for wide discussion and yet unlikely to be "dangerous." As typical subjects complying with the foregoing conditions, he suggested "The Chemical Worker," a discussion on whom might cover his carelessness and its results, and how best to guard against the latter, his health, and the methods by which it might be safeguarded, and the like; or "filtration," in respect of which he at least had many problems which he should be glad to discuss with other chemists; or again, such a subject as crystallisation might be widely discussed with general benefit and but the slightest risk that any secret could be disclosed. With reference to the complaint made by certain members that only one or two pages of the Journal were of interest to them, he suggested that that was too narrow a view of the matter, and that they might find it well worth while to study carefully the pages in which they were not "interested" in the narrower sense.

The HON. SECRETARY pointed out that as far back as April, 1914, he had proposed to the Committee a resolution which was agreed to unanimously:—

"That it was desirable in the interests of the Society to consider a scheme for the formation of a Chemical Club with suitable premises in London."

For various reasons that scheme could not be proceeded with at that time, but he believed that there were now large numbers of the members of the London Section who would be willing to support actively the furtherance of this proposal. The new list of members of the Section, now in proof, had a column attached showing the class to which they severally belonged. With the list of members would be published a more extended report than usual giving an account of the activity of the Section.

Dr. C. A. KEANE expressed himself thoroughly in sympathy with the proposal that steps should be

taken to effect some fuller opportunity than had existed in the past for the members of the Section to meet together on a social basis, and to get to know one another. It had been exceptionally interesting to hear so decided a demand for a development of this character, especially from the younger members of the Section, for this indicated the desire for real communal interest in the work of the Section which was bound to be of value. In the past the Committee of the Section had done their best to advance what they regarded as the best interests of the members, but as with all Committees and Councils the ideas for such advancement necessarily came from within the circle of the Committee itself, and they knew all too little of the views and desires of the bulk of the members of the Section. It appeared to him to be quite within the powers of the Section to take steps to initiate something in the form of a meeting place or club for social purposes, apart from the more formal gatherings for the reading of papers. The mutual relations of these functions of the Section was a matter which could well be left open for the present, but it was desirable that some beginning should be made which, if successful, should lead to important developments in the work both of the Section and of the Society as a whole.

The desirability of steps being taken to bring chemists more actively into association and co-operation had been in the minds of all during the period of this war crisis. The proposal under consideration formed a definite basis for this desirable objective and as such should be welcomed and supported by one and all of the many and varied interests represented in the Section.

Mr. BERNARD F. HOWARD said that many points had been raised that evening which could well form the basis for an evening's discussion at an informal meeting, *e.g.*, relation between chemists and directors, labour difficulties, etc.

Mr. Howard then proposed the following resolution, which was seconded by Dr. W. R. HODGKINSON, and carried:

"That a Committee be appointed to consider the steps that should be taken to form a Chemical Industry Club for the London Section of the Society of Chemical Industry, and to report to the Committee of the Section, and, subsequently, to a further Informal Meeting of the members of the London Section."

The following members were appointed to form a Committee—Messrs. H. E. Coley, A. H. Dewar, B. F. Howard, with the Chairman and Hon. Secretary *ex officio*.

Manchester Section.

Meeting held at Grand Hotel on Friday, December 1st, 1916.

MR. J. H. ROSEASON IN THE CHAIR.

THE ACTIVATED SLUDGE PROCESS OF SEWAGE PURIFICATION.

BY EDWARD ARDERN, M.Sc.

The rise and development of this method of sewage purification has been described in a series of three papers, entitled "The Oxidation of Sewage without the Aid of Filters," presented to this section of the Society during the past two years.

It was observed from the first that the purification process was subject to disturbance in the

presence of certain trade-wastes of inhibitory character.

For the purpose of investigating the effect of such trade effluents on the activated sludge process, the experimental plant employed previously when working with the Manchester sewage received at the Main Outfall Works, Davyhulme (a strong trade sewage), was transferred in July, 1915, to the Withington Sewage Works, Chorlton-cum-Hardy, where a purely domestic sewage is dealt with.

The preliminary results obtained during the period the activated sludge was being "built up" were, however, so remarkable that it was decided to postpone the trade-effluent trials pending a careful survey of the possibilities of the activated sludge process as applied to the purification of a weak domestic sewage free from manufacturers' effluents.

This communication is concerned with a brief account of the results of the investigation, which has extended over a period of fifteen months.

The plant employed consisted of wooden casks of 200 litres capacity (net). The aeration was effected by diffusing the air through a porous tile placed on the bottom of the cask. The air supply was always sufficient to maintain complete admixture and circulation of the sludge and sewage. The floating matters and grit had been removed from the sewage dealt with by prior screening and adequate detritus tank treatment.

The method of "building up" the activated sludge was that described in the last paper* on the subject.

For a period of nine days from the commencement of operations the cask was filled once each day, an aeration of 21 hours being allowed. The remaining 3 hours was occupied by quiescent settlement of the accumulated suspended matters, discharge of effluent, and refilling with sewage.

Subsequently the aeration period was reduced and the number of fillings rapidly increased without diminution in the purification effected, so that after the experiment had been in progress eighteen days, four fillings per day were allowed with an average of four hours' aeration. After operating for a fortnight in this manner the average aeration period was reduced to 2½ hours, and 5 fillings per day allowed for a period of eleven days. Eventually the cask received 6 fillings per day, with the following aeration periods: 3 fillings one hour, and the other 3 fillings, two hours, three hours, and four hours respectively, or an average aeration period of two hours.

Working in the manner described above, 15% by volume (measured after 2 hours' settlement) of partially activated sludge, *i.e.*, 30 litres or 6·6 gallons, were obtained from 2970 gallons of sewage dealt with during the first 31 days, which was increased to 31%, *i.e.*, 62 litres or 13·6 gallons, in the succeeding twelve days. At this point 5180 gallons of sewage had been treated in the cask. On this basis, the sludge production is equal to about 12 tons per million gallons of sewage treated.

The results obtained during this initial period were of such a character that it became of interest to determine whether they could be maintained indefinitely without regard to the establishment of active nitrifying organisms in the sludge.

At this stage, therefore, the partially activated sludge which had been accumulated was divided equally between two casks, one of which was operated with 6 fillings per day as previously, while the other was worked in such a manner as to allow a development of nitrifying organisms.

For this purpose, the first filling of sewage was aerated continuously until the free and saline ammonia content of the sewage had disappeared

* Ardern and Lockett (this Journ., May 30th, 1914, No. 10, Vol. XXXIII.).

* Ardern and Lockett (this Journ., Dec. 15th, 1914, No. 23 Vol. XXXIII.).

* Ardern and Lockett (this Journ., Sept. 30th, 1915, No. 18, Vol. XXXIV.).

* Ardern and Lockett (this Journ., Sept. 30th, 1915, No. 18, Vol. XXXIV.).

and nitrification was complete, which required 48 hours' aeration. Subsequent fillings were likewise aerated until the sewage was completely nitrified; the aeration period required during the following nine days, varying from 8 to 23 hours, dependent on the strength of sewage treated. Later it was found easily possible to allow 2 fillings per day with an average aeration period of 10 hours, and within 14 days of commencing to establish nitrifying organisms three fillings were being given (6 hours' aeration) with the production of highly nitrified effluents. Finally the quantity of sewage dealt with was increased by allowing 4 fillings per day with an average aeration period of 4 hours, at the same time maintaining a highly purified and well nitrified effluent.

It may be noted that nitrifying organisms were much more readily established in the sludge obtained from the Withington sewage than in that produced from the trade sewage at Davyhulme, e.g., the first filling of Davyhulme sewage usually requires 15 days' aeration in contact with the partially activated sludge for complete nitrification. Further, there is no ammoniacal fermentation of the sludge meanwhile or production of turbid effluents, and the alkalinity of the sewage is always sufficient to allow nitrification to proceed to completion.

During this period of complete maturing of the activated sludge, the cask containing the partially activated sludge continued to receive 6 fillings per day, but the total aeration periods had been reduced from 12 hours to 10 hours, divided as follows: four fillings one hour aeration and two fillings 3 hours' aeration, when the sewage was at its maximum strength, or an average of $1\frac{1}{3}$ hours' aeration per filling.

The average results obtained from the operation of the casks containing the two types of sludge over a prolonged period, embracing a great variation in temperature conditions, are given in the following table. The volume of sludge in each case varied from 20 to 25%, and the volume of purified effluent discharged after each filling was equal to 75% of the total capacity of the cask.

In general, the effluents obtained from the two casks were equally well clarified, although in some cases, especially during prolonged dry weather, when a stronger sewage was dealt with, the effluent yielded by the partially activated sludge exhibited a faint turbidity, whereas those from the fully activated sludge were invariably perfectly clarified.

The above results show that except for a somewhat lower albuminoid ammonia content, which is reflected in a reduced dissolved oxygen absorption, the difference between the effluent yielded by the fully activated sludge and that obtained from the partially activated sludge is confined to the amount of nitrification.

Their importance lies in the fact that they demonstrate that the activity of the sludge, so far as oxidation of carbonaceous matter and clarification is concerned, can be maintained without reference to the degree of nitrification.

This result is contrary to the experience gained in the earlier experiments when working with the trade sewage at Davyhulme; and means that if nitrification is not required, and it is certainly not essential, high-class effluents, easily within the standard suggested by the Royal Commission on Sewage Disposal, can be produced from domestic sewage by the activated sludge process, with a considerably reduced aeration period at consequently lower cost.

In view of this material difference between results obtained at Withington and Davyhulme, obviously it was important to ascertain whether similar differences were to be found with regard to the question of the effect of temperature on the purification process.

Operations with the two types of sludge were therefore extended throughout the winter and summer months.

In the following tables are given the results obtained when working (in each case) with from 20% to 25% by volume of sludge (measured after 2 hours' settlement) and removal of effluent

Results in parts per 100,000.

	Screened sewage.	No. 1 effluent.	Screened sewage.	No. 2 effluent.

There was no appreciable difference in appearance between the effluents obtained during the winter and summer months: in each case, they were invariably well clarified and contained only very small quantities of suspended matter.

It will be seen that the purification was not materially retarded by the low temperature experienced during February and March.

In the case of the partially activated sludge, however, there was a considerably reduced nitrification effect.

In the light of these results it would appear that the detrimental effect of low temperatures (below 10° C.) found when working with the Davyhulme sewage must be ascribed to the lowered vitality of the organisms present in the sludge, due to the constant presence of inhibitory trade waste, which renders them more susceptible to changes in temperature.

Activated sludge.

In the following table is given an average analysis of the activated sludge obtained from the Withington sewage together with comparative figures for the sludge produced from the Manchester sewage at Davyhulme, and from the Salford sewage.

Analysis of activated sludge (dry).

	Withington.	Manchester.*	Salford.†
Loss on ignition.	76.4	64.7	51.5
Mineral matter.	29.6	35.3	45.5
Total nitrogen (as N) .	6.0	4.6	3.75

Greasy matter, etc.— ether extract.	7.3	5.8	4.8

* Aldern and Lockett (this Journ., No. 10, Vol. XXXIII).
† S. E. Melling (this Journ., No. 23, Vol. XXXIII).

The activated sludge produced from the Withington sewage thus has an appreciably higher nitrogen content than either the Manchester or Salford sludge, due to some extent to the fact that the percentage of mineral matter is considerably less.

As stated in previous papers, the high percentage of nitrogen in activated sludge is one of the most important features of the process, in view of its direct concern with the question of the conservation of nitrogen.

Summary of results.

The results of the present investigation may be summarised as follows:—

1. That contrary to the opinion formed as the result of earlier experiments when working with a strong trade sewage, the maintenance of the activity of the sludge is not dependent on the stage to which nitrification is carried.
2. That when dealing with a sewage free from inhibitory trade effluents no appreciable loss of efficiency need be anticipated in this country during the winter months.
3. While the problem of disposal of the sludge remains to be fully developed, it would certainly appear from known data that the cost of dewatering and drying will be more than repaid by the value of the resultant dried sludge.

The investigation in regard to the effect of various trade effluents on the purification process is now well advanced and it is hoped that the results obtained will shortly be available for publication.

In conclusion the author has to thank Mr. H. Edwards (Withington Works Manager) for exercising general supervision, Mr. G. Smith (Laboratory Attendant) for intelligent operation of

the experimental plant, and Mr. C. Jepson, B.Sc., for able assistance in the analytical work involved. He is indebted to the Rivers Committee, Manchester Corporation, for permission to publish these results.

DISCUSSION.

THE CHAIRMAN enquired what was the effect of auto-digestion on the sludge and whether it was then more difficult to obtain a stable effluent.

Mr. S. E. MELLING was doubtful whether nitrification was, in all circumstances, vital. His experience of the continuous flow method of operation appeared to indicate that, by the use of 25% by volume of activated sludge, very satisfactory purification, notably in the colder winter months, could be obtained and maintained, practically without nitrification. He understood that the only effect of nitrification was to improve the stream into which the effluent passed by providing it with potential oxygen, which, however, was not the prime object of sewage purification. The point was, whether the elimination of the ultimate stage of more or less complete nitrification, would result in an appreciable saving of time, thus effecting economy in air consumption. One or two hours' treatment by the fill-and-draw method gave results very similar to those quoted in the paper, and conformed very satisfactorily to the suggested dissolved oxygen test of the Royal Commission. At the same time, the activity of the sludge was well maintained throughout. The figure of 3.8% of nitrogen (Salford sludge) given in the paper was now increased to 4.5% or thereabouts, and for all seasons of the year. Was it not possible to recover directly the nitrogen in the form of sulphate of ammonia. There was a very appreciable excess of nitrogen as compared with peat, and the latter, containing 2.0% of nitrogen and 40% of moisture, had, he believed, amply repaid for the recovery as the sulphate.

Mr. WILLIAM THOMSON asked whether it would be practicable to mix activated sludge with charred peat so that the large quantity of nitrifying bacteria in the sludge could be made available for the culture of vegetation. The charred peat would no doubt aid in the air drying of the sludge. He had Professor Bottomley's experiments in mind.

Mr. PERCY GAUNT enquired whether any difference in nitrogen content had been observed between the sludge employed for the maximum purification and the sludge employed for the less complete purification.

Mr. ARDERN in reply said the effect of auto-digestion of the sludge was to produce turbid effluents. In the absence of disturbance due to the presence of certain trade effluents, it was only met with during the initial period when nitrifying organisms were being established in the sludge by prolonged aeration periods. He agreed with Mr. Melling that nitrification was not essential and consequently in view of the fact, which had been established, that the activity of the sludge could be maintained without reference to the degree of nitrification, thoroughly well purified effluents could be obtained with a considerably reduced aeration period than was at first thought necessary, with consequent reduction in cost. He believed that the recovery of nitrogen by distillation of activated sludge was a practical proposition, but his view was that it would be better to utilise the dried sludge direct as a fertiliser. Its fertilising value had been thoroughly demonstrated by Dr. Bartow (Illinois University) and Mrs. Mumford (Manchester University). Activated sludge could, of course, be mixed with peat (either before or after inoculation) as suggested by Mr. Thomson, but seeing that the sludge itself contained appreciably more nitrogen than peat, it did not appear

desirable to do so. This suggestion, of course, raised the important question of soil inoculation which had been investigated by Professor Bottomley and others. He believed that the best results would be obtained by the direct use on the land of activated sludge with its normally high bacterial content, as there was every reason for believing that in addition to nitrifying organisms the sludge also contained nitrogen-fixing organisms. In devising means for drying or partially drying the sludge endeavour should therefore be made to avoid sterilisation.

The practical difficulty was, however, to maintain the organisms in the sludge in an active state particularly as the demand for manures was seasonal whereas the production of sludge would be regular all the year round. He had not observed any material difference in the nitrogen content of the partially and completely activated sludge.

Newcastle Section.

Meeting held at Bolbee Hall on Wednesday, December 13th, 1916.

MR. HENRY PEILE IN THE CHAIR.

A PORTABLE PLANT FOR THE DISTILLATION OF WOOD.

BY S. H. COLLINS, M.Sc., F.I.C.

The object of the plant is to obtain saleable products from branchwood, sawmill refuse, or other waste wood so as to clear the ground for other purposes such as replanting forest clearings or otherwise to utilise the ground previously covered with material of little value.

The plant is portable to permit its transport from place to place as may be required and consists of a cylindrical retort of $\frac{1}{2}$ -inch boiler plate, 16 feet long by 3 feet internal diameter, with a hinged door at each end falling downwards and supported so as to remain horizontal when open. The doors are closed by hinged bolts screwed up with nuts, and a strip of asbestos packing is used to make the doors as gas-tight as possible. Immediately outside the retort and forming part of it is a complete jacket of thin iron plate. The intermediate space 9 inches wide forms the flue and is divided horizontally by baffle plates into three parts so as to secure even and regular heating. There are two chimneys, one at each end, each fitted with a butterfly valve to control the draught. Outside the flue space is 2 inches of asbestos packing next the outside covering to retain the heat, and outside all is a light sheet iron cover. The whole is mounted on iron wheels so that it can be moved from place to place as required. Eight small tubes, $\frac{1}{2}$ -inch in diameter (to admit a thermometer), pass across the flues in order that the temperature may be observed from the outside. Owing to the breakage of thermometers and the expense and unsuitability of electrical appliances, a simple pyrometer of the calorimeter type is now used. The pipe which carries the products of distillation is connected with the top of the centre of the retort and after passing through a small tank, where much of the tar collects, proceeds in an upward direction to the cooling tank.

At the end nearest to the retort is a cross, or distributing pipe, to which are connected nine $1\frac{1}{4}$ -inch iron pipes extending the whole length of the condensing tank with a fall of about 3 inches to the far end. There they are connected with another cross pipe which has a small window to

permit of the inspection of the distillate as it passes into the collecting vessels. The cooling tank is filled with water but provision has to be made for supplying further water or for having some special cooling apparatus for the water in the tank. As the nine pipes above referred to are liable to become choked by the tar products from time to time, iron screw plugs are kept in the main pipes and holes with wooden spigots put in the cooling tank. A long iron rod serves to clean the pipes from time to time. Corrosion in the condenser is somewhat severe but experiments are being made to reduce this source of expense.

The collecting chamber consists of two closed 50-gallon barrels, each with one tap at the bottom and one tap about half way up. The lower tap is for the wood tar, and the upper one for the aqueous products of distillation. From the second barrel a 1-inch pipe is led on a rising gradient to the fire box, passing through a small tar trap on the way. This trap is intended to remove the remaining liquid products, whilst the whole of the gases pass into the fire box and assist in heating the retort. The fire box is built with ordinary white fire bricks and measures 2 feet 5 inches wide by 2 feet high and is about 4 feet long, connecting at the back with the retort flues. The only iron work about the fire box consists of the iron door and ten 1 inch iron fire bars set about 1 inch apart.

The speed at which the distillation proceeds is regulated more by the pressure than by temperature. For this purpose two simple water gauges are fitted on the side of the cooling tank connected by small pipes, one gauge with the upper cross pipe in the cooling tank and the other gauge with the collecting vessels. Under normal conditions these gauges should register 6 inches and 3 inches respectively. When the pressure on both gauges falls to zero it is an indication that the distillation is complete. Though extremely simple, these gauges are invaluable in working.

There are two precipitating tanks detached from the foregoing portions of the plant. They are used for converting the pyroligneous acid into acetate of lime. The first measures 5 ft. 6 in. \times 2 ft. 6 in. and the second is about 4 ft. 6 in. deep and 2 ft. 6 in. by 2 ft. 6 in. in section.

An iron tray about 4 feet square and 6 inches deep stands on the top of the fire box for the purpose of evaporating the solution of acetate of lime. This method is crude but more complex methods have been tried and given up.

The products of the distillation are charcoal, wood tar, pyroligneous acid, and water, together with various gases which are passed into the fire box and used for combustion.

The charcoal usually represents 25% of the total weight of the wood treated: that is from an average charge of one ton, 5 cwt. of charcoal is obtained. It is estimated that five to six cwt. of firewood is required for each charge, in addition to the gas produced. Coal has been used satisfactorily. The retort must be allowed to cool before being opened, otherwise the charcoal would be liable to ignite when coming into contact with the air. The charcoal as removed from the retort is stored in bulk or bags and can be sold readily.

The quality of the charcoal made depends upon the part of the tree from which the wood came and upon the temperature of the retort. Dense charcoals are preferred to light charcoals. The accompanying table shows that by keeping the proportion of bark low it is easy to get a charcoal with low ash. The conifers usually give a light charcoal. The proportion of gas left in the charcoal depends chiefly on the temperature of the retort.

From a ton of hardwood 18 gallons of water are thrown away and 30 gallons of pyroligneous acid obtained. The pyroligneous acid is transferred to

the first precipitating tank where it is mixed with 8 lb. of slaked lime for every 10 gallons of acid. As a rule, acetate of lime in solution is formed and a sludge is precipitated. After settling for a few days the solution is transferred to the evaporating tray for concentration, when it is either allowed to settle again or is filtered and finally evaporated to dryness, the solid residue, a grey substance of the consistency of chalk, forms the acetate of lime of commerce known as "brown acetate" or "grey acetate" according to purity. "Brown acetate" is approximately of 60% purity and "grey acetate" 80% purity. The former is used in the cotton industry and it is only the grey acetate that is of value in the manufacture of acetone. From a ton of hardwood about 4 gallons of wood tar is obtained. Its value is variously estimated from 6d. to 1s. per gallon, but

means of overcoming the difficulties. A Marriott dripping bottle supplies distilled water to the distilling flask which contains 2 grms. of the acetate and 15 c.c. of syrupy phosphoric acid. The Marriott bottle is adjusted to give a flow of about four drops a second. A flexible rubber tube joint, not shown in the sketch, facilitates this adjustment. The rate of boiling is arranged to maintain the liquid in the distilling flask at about the 50 c.c. level. The receiver contains 25 c.c. of $N/1$ soda, which at the end of the distillation is titrated with $N/5$ sulphuric acid using phenolphthalein as indicator. With pure acetates the whole of the acid distills in 300 c.c. but with very crude acetates as much as 1200 c.c. has been needed. In all cases it is necessary to continue the distillation for an extra 100 c.c. to make sure that all is over. The reason of this difficulty is that some acid of higher boiling point than acetic acid is always present. The proportion of such acid is greater in the cruder acetates than in the pure acetates.

Any slight draught on this apparatus only causes a small admission of air at the upper soda-lime tube to be followed by the expulsion of air at the lower soda-lime tube. This slight circulation of air is of great assistance in preventing bumping and frothing. The distilling flask may be about 200 c.c. capacity, the Marriott bottle about two litres, and the receiver about one litre.

Distilled water always contains some carbonic acid and it is difficult to prevent absorption during handling. The best way to surmount these difficulties is to perform a blank determination, which in my experience amounts to about one c.c. of $N/5$ acid. As the amount of alkali neutralised equals from 70 to 100 c.c., such a correction is not unreasonably large. No phosphoric acid spits over with this apparatus.

It is important to pack the retort as tightly as possible so that the maximum charge of wood can be put in, but sufficient space must be left to allow convection currents of hot gas to distribute the heat. If the pieces are straight and all of fair size, say 2 feet by 3 inches, as much as 25 cwt. can be put in, but if small and crooked wood is used, or quite small branches, the weight of material may be not more than 12 cwt. Sawdust is quite useless. To ensure freedom for the escape of the gas and vapours the small and crooked pieces are laid in the bottom of the retort and the large and straight pieces at the top. After the furnace is lit and the temperature in the retort commences to rise, water vapour is first given off. It is condensed and drawn off from the condensing chamber as soon as the pyroligneous acid begins to come over. This takes place when the temperature has reached a higher degree and simultaneously the wood tar also comes over. The window in the pipe connecting the cooling tank and the collecting chamber is most useful at this stage. The most suitable temperature for the distillation appears to be between 270° and 400° C. The temperature in the lower part of the flue space is about 450° C. and in the upper part of the flue space about 270° C., when the plant is in full working order. The plant is capable of dealing with about 120 tons of wood per annum or say three tons per week for 40 weeks with 12 weeks for bad weather, removing to new position, repairs, cleaning, etc. About two days are required for the complete distillation of each charge if the pieces are of fair size, and while the time required is less when the material is small, the weight of the charge is also less, and, in the end, the total production per week is less. In addition to the material consumed in the retort about 30 tons of firewood would be required for the furnace, or say 150 tons per annum in all. It is not easy to estimate how much small material would be derived from the felling area, but putting the

it would appear to be of much greater value for estate and local purposes than for sale in the open market. It is a very fine timber preservative. The acetate made by this plant has varied in composition but it seems likely that an acetate of about 70% could be obtained.

There is a good deal of literature dealing with the analysis of acetate of lime, especially about the year 1901, and the method adopted after many trials follows the lines already published. It is, however, desirable to emphasize the necessity of guarding against carbon dioxide from the air and to point out that the difficulties due to frothing with the cruder forms of acetate are not inconsiderable. The accompanying diagram provides a simple

amount at 5 tons an acre, the distillation plant would require the refuse material of 30 acres per annum to be fully employed. With regard to the question of labour, the work is not heavy but requires attention, and an elderly man has been quite able to manage all that is required. A handy motor circular saw would be a great help.

The actual accounts for twenty-two months are given in the following statement:—

FINANCIAL STATEMENT.

Period—July 1st, 1914, to May 1st, 1916.

RECEIPTS.			EXPENDITURE.		
11 tons 11 cwt 1 qr.	£	s. d.		£	s. d.
Charcoal = 65	9	6	Wages	61	8 11
Tar sold but not yet paid for	4	0 0	Time	1	13 6
In store, not sold—			Asbestos	0	14 7
Charcoal	10	0 0	Cartages	1	11 7
Tar	3	0 0		£65	8 7
Acetate	10	0 0	Experimental ...	70	0 0
	£95	9 6	Capital	212	8 1
				£277	16 8

Owing to the shortage of labour and bad weather, this plant has been out of action for several months at a time. Probably in normal times twice as much work could be done in a year as in the twenty-two months stated. However, a fair allowance for bad weather must be made.

The allowance of £70 for experimental expenses provides £20 for chemicals and preliminary trials, and £50 for early mistakes.

DISCUSSION.

Professor H. LOUIS said that for a great many purposes the charcoal may contain far too high a percentage of volatile matter, and he pointed out the large differences in the percentage of this constituent. He was surprised that the author of the paper had made no mention of wood spirit, as this probably would have been a valuable by-product could it have been saved. He did not agree with the suggestions of the author that sawdust was practically impossible to distil economically; he believed that by briquetting this waste material with wood tar, quite good

charcoal could be obtained. He described the large brick steel-lined furnaces that were used in Sweden and Russia for carbonising wood on a large scale.

He considered a high ash content of the charcoal a serious detriment to the value of this product, because if the charcoal were used in conjunction with the preparation of high quality iron, it was very liable to part with its phosphorus content, thereby contaminating the metal. He understood that if the timber remained in water for a considerable period of time, say twelve months, a large proportion of the saline constituents were leached out.

Dr. J. H. PATERSON pointed out that the firm he was associated with, and who took a large proportion of the make of the charcoal, required a fair proportion of volatile matter in the charcoal for close annealing furnaces; and in his opinion the percentage of volatile matter in the charcoal was purely dependent on time and temperature, and that there would be no difficulty in reducing the volatile matter to a very low figure if it were found commercially advisable.

The CHAIRMAN said he was much interested in the question of low volatile matter in the charcoal in connection with his work of manufacturing tungsten. He had found 5% or more of ash in the charcoal his firm were using, and he pointed out that it was very desirable that this should be very materially reduced.

Dr. G. P. LISHMAN inquired how long each distillation took, and what were the signs which indicated the completion of the operation.

Mr. COLLINS in reply said that his plant was, firstly, merely experimental, and secondly, able to be transported easily from place to place, a fact which was of course impossible with the bigger and more permanent forms of plant mentioned by Professor Louis. The charcoal was purposely made with a high content of volatile matter to suit their largest consumers. He pointed out from figures already stated in the paper that a large proportion of the ash appeared in the bark of the various woods carbonised, and that if the pieces of wood were freed from the bark, the general ash percentage of the charcoal would be very much less. It was not difficult to undertake this. The time of distillation varied very much according to the degree of moisture in the timber put into the distilling plant, and anything from 24 to 48 hours might be required to carry through the operation. The conclusion of the distillation could be well ascertained by the quantity of gas that was given off towards the end of the distillation being considerably reduced, and also the pressure on the whole of the plant considerably diminished at the time when the distillation was completed. He desired to acknowledge his indebtedness to Dr. Paterson for the great help he had given him, both in the design and working of the plant.

Industrial Notes.

SOME MODERN EVAPORATORS.

More than eighty years ago it was recognised that in the ideal evaporator the liquid should be concentrated as rapidly as possible and that it should be kept moving with a high speed: in order to accelerate its movement the use of a thin film of liquid should be maintained. Most of the modern forms of evaporating apparatus have been designed on these principles, and the following descriptions of three types of plant indicate how these principles have been applied.

The Kestner climbing film evaporator, illustrated in fig. 1, consists of two parts, the separator, S, and the calandria, the latter being composed

of a shell, M, containing evaporating tubes, R, about 23 ft. long and fitted into upper and lower tube plates. The liquor enters the apparatus at T and passes into the tubes, where it is heated by live or exhaust steam introduced at A. The column of vapour formed in the tubes travels upwards at a high velocity, drawing up with it a continuous film of liquor on the inner surface of the tubes. The mixed liquid and vapour emerge from the top of the tubes into the separator, S, where they strike the baffle plate, D, with such velocity that effective separation of the concentrated liquor and the vapour takes place. The concentrated liquor leaves the separator at L, and the vapour, after passing through the save-all, V, is drawn off through B. The outlet for condensed water is shown at E, while G is an air drain.

Where a large amount of liquor has to be concentrated, the evaporators are worked in multiple effect, and when a very high concentration is required for the finished liquor, the multiple effect may be followed by a single effect "finisher." In a plant for concentrating caustic soda, consisting of a triple-effect evaporator and a finisher, the thin liquor at 16° Tw. enters the first effect after preliminary heating by vapour produced from the liquor itself. Leaving the triple effect at 100° Tw., the liquor is passed

to settling tanks where salts are deposited, and then goes to the finisher, where it is concentrated to contain 60% Na_2O .

When very viscous liquids have to be dealt with, the climbing film is not always convenient for the last effects, and for these a falling film evaporator may be used. In one type of this apparatus one set of tubes is of the climbing film type, and the liquid coming from the top of these passes down a second set of tubes in a descending film to the separator, which is connected with the lower part of the apparatus.

The Söderlund and Boberg evaporator, illustrated in fig. 2, consists of a shell, A, containing a calandria, B. The liquid is raised by the pump, F, from the lower portion, G, of the shell into the tray, H, whence it passes through nozzles in the top of the tubes, C, and is distributed in a thin sheet over the interior of the tubes. The liquid is heated by compressed steam introduced into the upper part of the calandria. The concentrated liquid collects in the bottom of the shell, fresh liquid being supplied by the constant-level feed, I. The steam evolved in the tubes, C, is separated from liquid by the baffles, J, and passes through the steam main, K, to the compressor, L, where it is compressed sufficiently to raise its temperature to the required degree and used for heating the tubes after addition of the necessary quantity of make-up steam at M. The condensed water from the outside of the tubes is drained off through N, and used to heat the incoming liquor in the counter-current regenerator, O. A very high efficiency is claimed for this apparatus in virtue of the fact that the difference of temperature between the boiling liquid and the heating steam is very small (from 1° to 3° C.). A plant on this system is being erected in Sweden for treating the waste liquors from wood pulp manufacture.

FIG. 2.

Another type of evaporator working on similar principles is the Prache and Bouillon "thermo-compressor," shown in fig. 3. The liquid to be concentrated enters the apparatus at A, passes through the heating tubes B, and thence through the horizontal tube into the lower part of H, where it is distributed in the tubes, G, the concentrated liquor falling into C and being drawn off at D. Live steam for heating the tubes enters

FIG. 3.

at E, drawing with it through F steam from H; the mixture flows around the tubes, G, and thence passes up into the chamber, H, a part returning through the tube, I, to be used again for heating the tubes G, and the remainder flowing through K to the heater, B.

The same firm has designed another type of evaporating plant (fig. 1) which has been used successfully for concentrating high-density sugar syrup, and is heated by steam at very low pressure. The liquid to be concentrated enters at A, passes upwards through the tubes, G, which it only partially fills, to the ebullition chamber, F, and thence the concentrated liquor flows back through

FIG. 1.

the circulation tube, H, and out at the bottom part, B, of the level-adjusting device. The heating steam, introduced at C, passes around the outside of the tubes, G, the condensed water being discharged at D and the non-condensable gases at E. Rapid evaporation of liquid is secured by reason of the rapidly moving mixture of liquid and vapour which occupies the upper parts of the tubes.

PRICES OF CHEMICALS IN 1916.

The "Annual Trade Review," issued as a Supplement to the January number of the "Chamber of Commerce Journal," contains an interesting article by J. C. Umney, dealing with the drug and chemical trades in 1917.

Broadly the drug and chemical trades have laboured in 1916 under the same general drawbacks as operated in 1915, such as stringency in labour, difficulties in home transport and in shipping facilities for abroad, export restrictions, and so on. The year has brought its own particular problems; among these have been difficulties in connection with the supply of alcohol, which have been overcome so far, although the article and the innumerable preparations into which it enters cost more. There have also been increasing difficulties in obtaining supplies of sugar for pharmaceutical purposes, and the restrictions on the sale and use of glycerin. Despite all the obstacles, however, the drug, fine chemical and essential oil trades have done well. War's demands on manufacturers and wholesale distributors have been heavy; export business, too, has increased, especially to Russia. There has also been a distinct increase in production of fine chemicals previously made abroad, and as time goes on we shall witness further extensions.

The course of prices in the synthetic group shows our experience in a department formerly mainly supplied by Germany. In leading items of this classification, 1916 prices summarised show as follows:—

lb.	Open.	Close.	Highest.	Lowest.	Pre-war rate.
	s. d.	s. d.	s. d.	s. d.	s. d.
Acetanilide	7 0	2 0	9 0	2 9	0 11

Phenolphthalein	37 6	85 0	150 0	37 6	5 6
Resorcin	70 0	145 0	145 0	70 0	2 6
Salicylic acid ..	20 0	5s. 9d.-6s.	22 0	5 9	0 11
Salol	46 0	11 0	48 0	11 0	2 4
Soda salicylate ..	21 0	6 0	21 0	6 0	1 2
Sulphonal	45 0	30 0	45 0	22 6	9 9

It will be seen that the general upward movement in this group in 1915 was not sustained all round in 1916. Several of these substances indeed, show substantial reductions, owing to increased production, as in the case of the salicylates, hexamine, sulphonal, and vanillin, or because of a cheaper cost of raw material, as in acetanilide and hydroquinone. On the other hand, efforts to make such substances as phenacetin have not fructified sufficiently to relieve to any extent the stringency in supplies, and consequently the value has increased considerably; similarly as regards guaiacol carbonate, barbitone, phenolphthalein, and resorcin.

In the alkaloids, prices were:—

	Open.	Close.
	s. d.	s. d.
Atropine sulphate, oz.	120 0	115 0
Cocaine hydrochlor., net oz.	14 0	21 0
Codeine, pure cryst., oz.	22 0	21 0
Caffeine, pure, lb.	25 0	30 0
Morphine hydrochlor. pulv., oz.	13 3	13 3
Quinine sulphate, oz.	3 3	2 6
Pilocarpine hydrochlor., oz.	17 0	24 0
Sparteine sulph., oz.	36 0	72 0
Strychnine, pure cryst., oz.	2 6	3 4
Theobromine, pure, lb.	55 0	70 0

Of the above atropine sulphate at one time touched 165s. per oz., and cocaine hydrochlor. 27s. 6d. (compared with 4s. 5d. just before the war broke out). The highest price for quinine sulphate from dealers was 43s. 3d. per oz., and the lowest 2s. 2d. Pilocarpine steadily advanced and sparteine took a steep upward move in December. Strychnine has gradually advanced in sympathy with the higher cost of *Nux vomica*, accentuated by the shortness in supply.

Reviewing the more important heavy chemicals, the following epitome is given on page 73:—

Alum production has suffered from the shortage of sulphuric acid. The big rise in arsenic reflects the higher cost of mining and freights. Heavier demand has lifted prices of ammonium sulphate. War's requirements have depleted the supplies of bleaching powder available for ordinary purposes. Higher freights account for several rises in borax and boracic acid. Iron and copper sulphate reflect the dearer cost of the metals and acid. Potashes have been very scarce, especially Montreal certificated. Potassium chlorate prices have been sympathetic to the large inroads on supplies for war needs. Potassium permanganate, being rather more plentiful, declined until the autumn, when, however, a substantial recovery set in. The difficulty in getting consignments from Chile influenced an upward trend in nitrate of

Santonin, lb.	7 15 0	8 0 0
Saccharin, 550, lb.	3 13 0	6 10 0
		(makers)
		10 0 0
		(secondhands)
Turpentine, cwt.	2 12 0	2 13 6

Bismuth subnitrate in second hands was lifted to 15s. per lb. at one time, the works themselves being full up with orders and often unable to supply for immediate delivery. In refined camphor there was a remarkable run-up in prices following on several advances in the Monopoly quotations for Japan crude. Cod liver oil prices, for the greater

part of the year, have been practically prohibitive of business (at one time as much as \$45s. per barrel c.i.f. was quoted for one brand), and have provided a good opening for the retined Newfoundland article. Formaldehyde at one time attained 125s. per cwt. Milk sugar has more than doubled its value owing to the shortage of receipts. There was a big drop in bromides, which, at American instigation, were on one occasion subjected to a most dramatic reduction.

A few spot prices of the leading essential oils and allied articles are also abstracted from "The Perfumery and Essential Oil Record" are given below.

DRUGS AND CHEMICALS FOR AUSTRALIA.

The Chemical Trade Section of the London Chamber of Commerce desires to give publicity to the fact that the attention of the British exporters of drugs and chemicals has been drawn by a Government Authority in Australia to the desirability that all drugs and chemicals exported from the United Kingdom shall be in all respects up to the British Pharmacopœia standards. It is believed that German exporters, before the war, complied strictly with this condition, and it is therefore suggested that if business is to be maintained after the war the correct standard of quality must be strictly adhered to by British firms, especially in view of the probability that enemy countries will, at all costs, make strenuous efforts to renew those business relations which they have temporarily lost.

THE WORLD'S COPPER SUPPLIES.

The output of copper in the various producing countries is reviewed in a recent issue of the "Engineering and Mining Journal." The world's production showed a steady increase up to 1912, when it reached a maximum at 1,021,100 tons. The term "production" includes copper obtained and obtainable from the ore mined. In 1913 the output fell to 1,002,300 tons, chiefly owing to the internal troubles in Mexico, where production declined from 73,700 to 52,800 tons. The principal producers in 1913 were: United States, 557,400 tons; Japan, 73,200; Spain and Portugal, 51,700; Mexico, 52,809; Australia, 47,300; Chile, 40,000; Canada, 34,900; Russia, 33,900; Peru, 25,700; Germany, 25,300; Serbia, 6,100; and Katanga (Belgian Congo), 6,000 tons. As showing the increase in output during the last quarter century, the figures for 1897 for some of the countries are given as follows:—United States, 224,000 tons; Japan, 13,500; Australia, 17,300; and Chile, 22,300 tons. The present output of ore at Chuquibambata is said to be 10,000 tons daily, the mine here being the largest in the world. The production of copper in most countries decreased in 1914, but rose again in the following year, as shown below:—

Country.	Production.	
	1911.	1915.
	Tons.	Tons.
United States	525,500	646,200
Mexico	36,300	31,000
Japan	72,800	75,000
Spain and Portugal	37,100	35,000
Australia	37,600	32,500
Chile	40,900	47,400
Canada	34,000	26,000
Russia	31,300	26,000
Germany	30,500	35,000
Peru	23,600	32,400

The total production in 1914 and 1915 was 927,200 and 1,061,600 tons, respectively.

The following figures, relating to 1913, are of interest as showing the output of mines, the activity of metallurgical works, and the copper consumption in the different countries:—

Country.	Output of mines.	Copper produced in metallurgical works.	Copper consumption.
	Tons.	Tons.	Tons.
United States	557,400	589,100	318,100
Germany	25,500	41,000	259,300
United Kingdom	300	52,100	110,300
France	—	11,900	103,600
Russia	33,900	34,200	40,200
Austria-Hungary	4,100	2,300	39,200
Italy	1,600	2,300	31,200
Belgium	—	—	15,000

Obituary.

ANDREA ANGEL.

The profound sympathy of all engaged in chemical industry will be extended to the relatives of Dr. Andrea Angel, who lost his life in the disastrous explosion which occurred in the East End of London on January 19th. Dr. Angel, who was educated at Christ Church, Oxford, was the chief chemist at the munitions factory in which the explosion happened; when the fire broke out he warned the operatives to leave and himself heroically returned to assist in the attempt to subdue the outbreak, though he must have known that in so doing his own life would be sacrificed.

Journal and Patent Literature.

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—

English.—6d. each, to the Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C.

United States.—1s. each, to the Secretary of the Society, who has to furnish the U.S. Patent Office with the following data:—Patent number, date, name of patentee, and title of invention.

French.—1 fr. 05 c. each, as follows: Patents dated 1902 to 1907 inclusive, Behn et Cie., 56 Rue Feron 8, Paris (Se); Patents from 1908 to date, L'Imprimerie Nationale, 87, Rue Vieille du Temple, Paris.

I.—GENERAL; PLANT; MACHINERY.

PATENTS.

Grinding mill for wet or dry substances. T. Breakell, Wirksworth. Eng. Pat. 16,511, Nov. 23, 1915.

Is a horizontal grinding mill the lower, positively driven member, which is contained in a fixed casing, has a central cone projecting from its upper face which works in connection with a conical depression formed in the centre of the under surface of the upper or frictionally driven member. The latter is mounted eccentrically to the former in a spherical bearing which is carried by a hinged cover. A scraper is provided which bears against both members at the point where their outer edges coincide.—W. H. C.

Ball-grinding machine. E. Hamis, Tegel, Germany. U.S. Pat. 1,205,531, Nov. 21, 1916. Date of appl., Sept. 8, 1916.

A PAIR of vertical rotating discs are arranged parallel to one another with annular grooves on their inner faces. A pair of relatively fixed grinding discs are arranged between the rotating discs, with grooves on their outer faces registering with the first mentioned grooves. The relatively fixed discs have a limited axial and radial movement and are

pressed apart preferably by springs contained in recesses in a fixed central plate between them. A charging recess is formed by cutting away the fixed grinding discs and central plate.—W. F. F.

Separators; Centrifugal.—T. E. Brown, New York. Eng. Pat. 102,284, Jan. 26, 1916. (Appl. No. 1,277 of 1916.)

THE opening and closing of the outlet for the solid material, and the operation of the ejecting mechanism, are effected positively by fluid pressure from devices external to the centrifugal machine and controlled by valves actuated by solenoids.—W. H. C.

Furnaces. H. J. Yates, Birmingham, and S. N. and E. R. Brayshaw, Manchester. Eng. Pat. 102,318, Apr. 12, 1916. (Appl. No. 5333 of 1916.)

IN a gas- or oil-fired furnace several primary combustion chambers are arranged along one side of the furnace with ports leading into the latter. The waste gases leave the furnace by ports on the opposite side and pass by separate conduits to a main waste gas flue which passes longitudinally beneath the floor of the furnace. The secondary air is preheated by the waste gas in regenerators placed in the main waste gas flue, or between it

and the waste gas conduits, and then passes under pressure through nozzles at the rear of the primary combustion chambers and impinges on the flame, forcing the latter into the furnace.—W. H. C.

Filters; Method of operating —. C. S. Bradley, New York. U.S. Pat. 1,206,207, Nov. 28, 1916. Date of appl., Mar. 13, 1913.

A CHARGE of liquid is filtered through a stationary filtering medium and the greater part of the cake is removed by a scraper. A fresh charge of liquid is introduced, and the residue of cake is removed by applying pressure within the filtering medium substantially equally towards and away from the support of the filtering medium, whereby displacement is avoided and the residue of cake is blown into and mixed with the new charge.

—W. F. F.

Condenser; Surface —. A. Siegel, Charlottenburg, Germany, Assignor to General Electric Co. U.S. Pat. 1,206,605, Nov. 28, 1916. Date of appl., Apr. 3, 1914.

GROUPS of cooling tubes are provided with separate valve-controlled conduits for admission and discharge of cooling fluid in such a way that the groups may be connected in series or parallel or any group may be cut out. A partition in the enclosing casing separating the groups from one another is provided with an opening controlled by an externally operated valve.—W. F. F.

Drenching a material with a liquid; Apparatus for periodically — and thereafter draining it therefrom. A. T. Eyton, Nelson, and F. J. Henderson, Vancouver, B.C., Canada. U.S. Pat. 1,206,685, Nov. 28, 1916. Date of appl., Oct. 20, 1915.

A SERIES of vats are arranged in steps and each contains a perforated tray clear of the bottom, which carries the material to be treated. Each vat is connected with the one below it by a siphon which has one leg below the perforated tray, passes through the wall of the vat near the top, and terminates in the vat next below. The treating liquid which is supplied to the uppermost vat thus empties itself through all the vats to a tank at the bottom, from which it is periodically transferred to the uppermost vat. A draining valve is provided in the bottom of each vat.—W. F. F.

Atomising fused materials; Process and apparatus for preventing so-called "cold-blowing" in —. "Metallatom" Ges. m.b.H., Köln-Ehrenfeld. Ger. Pat. 291,850, May 28, 1914.

THE jet through which the fused material issues is surrounded by a slot through which hot air or hot waste gases are drawn by the injector action of the compressed gas used as atomising agent; the hot air or gas thus forms a mantle around the fused material and protects it from direct contact with the cold compressed gas.—A. S.

Thermostats. C. E. Hearson, London. Eng. Pat. 102,538, Feb. 9, 1916. (Appl. No. 1920 of 1916.)

Dehydrator. C. Robinson, Mount Vernon, N.Y., Assignor to Metallurgical Engineering and Process Corporation. U.S. Pat. 1,208,014, Dec. 12, 1916. Date of appl., Nov. 29, 1910.

SEE Eng. Pat. 2806 of 1913; this J., 1914, 341.

Condensing and vacuum-producing; Device for —. E. Josse and W. Gensecke, Assignors to Ges. für Kälteindustrie m.b.H., Berlin. U.S. Pat. 1,208,325, Dec. 12, 1916. Date of appl., July 9, 1915.

SEE Eng. Pat. 9724 of 1915; this J., 1916, 914.

II.A.—FUEL; GAS; MINERAL OILS AND WAXES.

Pulverised coal; Use of —. (1) J. E. Muhlfield. Amer. Soc. of Mech. Eng. (2) J. W. Fuller. Amer. Iron and Steel Inst. Engineering, 1917. 103, 3—4.

(1) ANY solid fuel having, in dry pulverised form, two-thirds of its content combustible can be used for generating steam. The best results are obtained when the fuel is mechanically dried and crushed so that the moisture does not exceed 1%, and 95% passes through a 100-mesh and 85% through a 200-mesh screen. The average cost of preparation is estimated at about 1s. per ton. Tests carried out with a ten-wheel type of goods locomotive gave an average of 12.8 ton-miles per lb. of coal. The prepared fuel is thoroughly mixed with air under pressure and blown into the fuel and air mixers, where additional induced air is supplied. The final mixture, now in combustible form, is drawn into the furnace, the flame produced attaining a maximum temperature of 2500°—2900° F. (about 1370°—1590° C.). The use of pulverised fuel, besides eliminating smoke and other disadvantages, is stated to increase the draw-bar horse-power per unit of weight, to improve the thermal efficiency of the locomotive as a whole, to reduce the non-productive time at the terminals, to reduce labour, and to produce more economical operation; moreover, otherwise unsuitable fuels can be utilised. An illustration of a triple burner and fire-pan as applied to locomotive firing is given. (2) Pulverised coal has been applied very satisfactorily to various kinds of metallurgical furnaces. Open-hearth furnaces are in operation, with powdered coal, having a fuel consumption equal to the best producer-gas practice. Coal can be pulverised and delivered to the furnace at a little more than half the cost required with gas producers. It is believed that there would be from 1 to 2% less oxidation in pig-iron and scrap in melting down from the cold state. Coal for this purpose should be high in volatile matter and low in ash. The discussion revealed the fact that in using pulverised coal, suitably designed chequers and slag pockets were necessary. Illustrations of a coal dust feeder and burner for steel furnaces are given.—J. E. C.

Gas works retort carbon.

THE Minister of Munitions has ordered that no person shall, as from 11th January, until further notice, purchase or take delivery of any gas works retort carbon except under and in accordance with the terms of a permit issued under the authority of the Minister of Munitions; and, further, that no person shall, as from the date mentioned, until further notice, sell, supply, or deliver any gas works retort carbon to any person other than the holder of such a permit. All applications for a permit in connection with this Order should be addressed to the Director of Materials (A.M.2.F.W.II.), Armament Buildings, Whitehall Place, London, S.W.

Carbon bisulphide; Removal of — from coal gas. H. Wanner. J. Gasbeleucht., 1915, 58. 456—457. Chem.-Zeit., 1916, 40, Rep., 414.

GAS coke, lignite coke, coke from sewage sludge, and kieselguhr were found to be incapable of absorbing carbon bisulphide from coal gas, and only a very small quantity was absorbed when the gas was passed over powdered retort carbon, boghead cannel, or hard pitch, or sawdust. By means of wood charcoal in small pieces both carbon bisulphide and hydrogen sulphide were removed to a considerable extent. For example, using 1 kilo. of charcoal per 5—6 cb. m. of gas, the total sulphur content of the gas was reduced from

73 to 20 grms. per 100 cb. m. The charcoal after use could be revived by heating at 105° C. for 2 days.—A. S.

Pentanes and hexanes; Thermal and pressure decomposition of—. G. Egloff, Met. and Chem. Eng., 1916, 15, 692—696.

The mixture of pentanes and hexanes used was derived from petroleum ether after removal of unsaturated hydrocarbons; the mixture had sp.gr. 0.656 at 15.5° C., and on distillation yielded: below 40° C., 36.0; 40—60° C., 29.6; and 60—70° C., 31.2%. It was subjected to temperatures of 450°, 500°, 650°, and 725° C. and pressures of 1 and 12 atmospheres, and the recovered oil examined for benzene, toluene, xylene, naphthalene, and anthracene. The percentage yield of recovered oil decreased with increase of temperature and pressure. The maximum yield occurred at 450° C. and 1 atmos. pressure. At 650° C. and 12 atmos. pressure, and at 725° C. and 1 atmos., the starting oil decomposed completely to carbon and gas. The percentage of benzene in the recovered oil increased as temperature and pressure were increased, the maximum of 15.1% being found at 650° C. and 1 atmosphere. The toluene and xylene content of the recovered oil decreased with increased temperature and pressure, the maximum being 0.9% for toluene and 8.2% for xylene, both at 450° C. and 1 atmosphere. Naphthalene and anthracene in the recovered oil increased with temperature and pressure, a maximum of 5.6% for naphthalene and 4.2% for anthracene being obtained at 650° C. and 1 atmosphere. The yields of benzene, toluene, and xylene calculated on the basis of the original oil decreased with increase of temperature and pressure; the highest yields were 3.2% for benzene, 5% for toluene, and 5.9% for xylene, all at 450° C. and 12 atmospheres. Naphthalene and anthracene increased with increasing pressure; the maximum for naphthalene was 1.7% and for anthracene 1.2%, both at 500° C. and 1 atmosphere. The mechanism of aromatic formation from pentanes and hexanes is probably as follows: Pentanes and hexanes $\rightarrow C_6H_{10} + CH_4 \rightarrow C_2H_4 + C_4H_6 \rightarrow$ naphthenes (alicyclic hydrocarbons) \rightarrow aromatic hydrocarbons. —T. H. B.

PATENTS.

Briquettes of coke, turf, iron or other ores, or the like; Manufacture of—. E. Kleinschmidt, Frankfurt, Germany. U.S. Pat. 1,207,180, Dec. 5, 1916. Date of appl., Oct. 3, 1916.

BRIQUETTE material is fed into a rotary inclined drum, which is moved so as to give a rising and falling motion to the material, and a binding material is sprayed into one end of the drum in a direction at right angles to the falling motion of the contents.—J. E. C.

Fuel, and process of making the same. C. Baskerville, New York, Assignor to S. Sternau and Co., Brooklyn, N.Y. U.S. Pat. 1,208,265, Dec. 12, 1916. Date of appl., Jan. 11, 1916.

A JELLIFIED mixture of alcohol and a salt, e.g., calcium acetate, is mixed with a weakly ionisable acid substance to prevent the formation of an alkali during combustion.—J. E. C.

Coke oven recuperative systems. J. E. Christopher, Hindley, Eng. Pat. 102,422, Mar. 18, 1916. (Appl. No. 4041 of 1916.)

Two regenerative chambers, J, are arranged side by side beneath each oven. Waste gases from the sole flue, H, pass through one or other of these chambers, the remaining chamber serving to heat

the air passing to the flues. The dampers, M, are reversed periodically by the levers, N, the change in direction of currents being shown in Fig. 2. The use of two chambers for each oven brings about a condition in which the hot waste products are always sandwiched between the air chambers and

FIG. 1.

FIG. 2.

vice versa, whilst the horizontal partition, V, lengthens the passage of waste gases and air. Thus a portion of heat is recovered by transference through the dividing wall, T, as in the usual continuous recuperative systems, the remaining portion being absorbed from actual contact with checkerred filling material in the chambers, J. The course of gas and air in the flues is continuous, whilst the fluctuation of temperature of the hot air is less marked than in the usual reversing systems. A discontinuance of reversal of the dampers, M, converts the system into a continuous recuperator. All reversing levers, etc., are on one side of the battery, and individual ovens and regenerators are accessible for repairs.—J. E. C.

Coke oven; By-product—. G. H. Benjamin, New York. U.S. Pat. 1,205,698, Nov. 21, 1916. Date of appl., Dec. 11, 1911.

THE heating flues are of such size as to permit free development of flame and are heated by burners utilising gas and air at a pressure of 1 to 1½ lb. per sq. in.—J. E. C.

Smokeless fuel; Distillation of carbonaceous material for the production of—and recovery of by-products. R. S. Richards, Woodford, and The Smokeless Fuel Syndicate, Ltd., London. Eng. Pat. 15,933, Nov. 11, 1915.

TRough sections mounted on a chain conveyor are carried in a closed circuit through an upper and lower longitudinal chamber surrounded by masonry. The conveyor is charged with fuel at one end and discharges at the other. The fuel is heated by combustion chambers disposed between the upper and lower chamber.—J. E. C.

Carbonising fuel. H. L. Doherty, New York. U.S. Pat. 1,207,723, Dec. 12, 1916. Date of appl., Jan. 29, 1915.

FUEL is carbonised in a closed conduit with comparatively long end extensions. The volatile matter is expelled in an intermediate localised section of this conduit, the tarry constituents being condensed in the upper end extension. The flow of the gas current is periodically reversed to carry back the condensed tar into contact with hot fuel, and the re-vaporised tar is withdrawn from the conduit.—J. E. C.

Gas; Manufacture of combustible—. H. L. Doherty, New York. U.S. Pat. 1,207,724, Dec. 12, 1916. Date of appl., Jan. 29, 1915. (See preceding abstract.)

FUEL is passed through a comparatively long vertical conduit, and in an intermediate section a

oxidising mixture of air and steam is introduced, thereby generating combustible gas in this region. This combustible gas passes through the unburnt fuel and becomes cooled. The cooled gas is then passed into contact with that portion of the fuel body which has been subjected to partial combustion.—J. E. C.

Gas engine cylinders; Removing carbon from —. W. K. Rogers, Assignor to W. E. Tucker and H. Rigdon, Forest Hill, Md., and C. B. Whitaker, San Francisco, Cal. U.S. Pat. 1,205,264, Nov. 21, 1916. Date of appl., July 23, 1915.

CARBON deposits in gas engine cylinders are removed by introducing a water-free mixture of wood alcohol and ammonia.—J. E. C.

Gas washing, cooling, and drying apparatus. F. Balassa, Assignor to Hungarian Banking and Trading Co., Ltd., Budapest, Austria-Hungary. U.S. Pat. 1,205,964, Nov. 28, 1916. Date of appl., Dec. 27, 1913.

GAS is supplied by a pipe projecting through the cover of a vertical cylinder containing coke, and passes through the coke to the perforated lower end of an inner concentric cylinder containing iron filings. The purified gas is withdrawn from the top of the inner cylinder. A concentric water supply pipe within the gas supply pipe carries a sprayer immediately below the cover, which sprays the cooling water at right angles to the flow of gas.—W. F. F.

Hydrocarbon gases; Purifying and improving —. P. A. and E. A. Starke, Assignors to Standard Oil Co., Richmond, Cal. U.S. Pat. 1,206,156, Nov. 28, 1916. Date of appl., Jan. 24, 1916.

GASEOUS hydrocarbons of the general formula C_nH_{2n+2} are purified by passing over a catalyst consisting of a mixture of an alkaline earth, an alkali, and a metal of the iron group, at a temperature between 1000° F. (about 540° C.) and 1600° F. (870° C.). Nitrogen compounds are separated and a mixture of hydrocarbons and aromatic compounds left, from which the latter are separated by cooling and subjecting to a pressure of 500 lb. per square inch. The remaining gas is improved in heating and illuminating power.—B. V. S.

Fuel-briquetting plant and the like. T. Rigby, Dumfries, Assignor to Wetcarbonizing, Ltd., London. U.S. Pat. 1,208,658, Dec. 12, 1916. Date of appl., Feb. 16, 1912.

SEE Eng. Pat. 14,621 of 1911; this J., 1912, 1021.

Coke-ovens and the like; Method of heating —. R. Geipert, Assignor to Dessauer Vertikal Ofen Ges., Berlin. U.S. Pat. 1,208,134, Dec. 12, 1916. Date of appl., Apr. 10, 1914.

SEE Fr. Pat. 471,644 of 1914; this J., 1915, 414.

Gas producers. P. A. J. Cousin, Loos-lez-Lille, France. Eng. Pat. 101,640, Dec. 9, 1913. Under Int. Conv., Dec. 9, 1912. (Appl. No. 13,937 of 1916.)

SEE Addition of Dec. 9, 1912, to Fr. Pat. 435,532 of 1911; this J., 1913, 647.

Gas producer. J. Stewart, Alfreton, and W. Stewart, Motherwell. U.S. Pat. 1,208,689, Dec. 12, 1916. Date of appl., Nov. 18, 1910.

SEE Eng. Pat. 20,858 of 1909; this J., 1910, 1103.

Utilisation of aluminium chloride residues [from oil refining]. U.S. Pat. 1,206,874. See VII.

Continuous gas-calorimeter. U.S. Pat. 1,205,704. See XXIII.

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

PATENTS.

Destructive distillation; Apparatus for —. J. W. Barnes, Lake Charles, La. U.S. Pat. 1,208,453, Dec. 12, 1916. Date of appl., Feb. 15, 1916.

THE apparatus comprises a retort, the vapour from which is fractionally condensed, whilst liquid products pass through a pipe at the bottom of the retort to a second still, the vapour from which is also fractionally condensed in a separate cooling system. The gases from both cooling systems are withdrawn by an exhaustor and pass to a common gas bell.—J. E. C.

Heating furnace; Continuous —. C. D. Barnhart, Brooklyn, N.Y., and W. H. Jacobi, East Orange, N.J., Assignors to W. S. Rockwell Co., New York. U.S. Pat. 1,205,503, Nov. 21, 1916. Date of appl., Dec. 17, 1915.

IN a furnace for heating, annealing, etc., a horizontal heating chamber is provided with means for heating a horizontal zone in the upper part. The gases are dispersed below this zone, and the articles to be heated are transported by an endless conveyor below the heating zone and parallel with the same.—J. E. C.

Tank heating furnace. W. Seringeour, Assignor to Mires Fuel Oil Equipment Co., Lancaster, Pa. U.S. Pat. 1,206,383, Nov. 28, 1916. Date of appl., Oct. 1, 1914.

A HEATING furnace comprises a long narrow chamber having a channel at the bottom and vents at the top. A tank is mounted eccentrically in the chamber nearer the vents than to the channel. The channel communicates with and is heated by a series of combustion devices.—J. E. C.

Arc-lamps; Electrode for —. W. R. Mott, Lakewood, Ohio, Assignor to National Carbon Co., Cleveland, Ohio. U.S. Pat. 1,205,377, Nov. 21, 1916. Date of appl., Nov. 8, 1911.

AN arc lamp electrode containing carbon and rare-earth titanates is claimed.—J. E. C.

III.—TAR AND TAR PRODUCTS.

Polycarboxylic acids of aromatic hydrocarbons; Preparation of — by means of dialkylindanediones. M. Freund and K. Fleischer. Z. angew. Chem., 1916, 29, 421.

AROMATIC polycarboxylic acids are readily obtained by oxidation with nitric acid of dialkylindanediones, which are themselves obtained by the action of dialkylmalonyl chloride on aromatic hydrocarbons in presence of aluminium chloride, according to the scheme:

IN this way certain otherwise inaccessible acids were synthesised, including 1,2,3,4-benzenetetracarboxylic acid (mellophanic acid) from *p*-xylene; 1,2,3,5-benzenetetracarboxylic acid (prehnitic acid) from *m*-xylene; α - α , α - β , and β - β -dicarboxylic acids of naphthalene; and also benzene-penta- and hexa-carboxylic acids from *p*-xylene by a double application of the reaction, the ketonic intermediate product being reduced to a hydriindene which in the one case was treated with acetyl chloride and in the other case with dialkylmalonyl chloride, and the products oxidised as above described.—G. F. M.

Thermal and pressure decomposition of pentanes and hexanes. Egloff. See II A.

PATENTS.

Nitro-compounds ; Manufacture of—, A. Heine-mann, Birmingham, Eng. Pat. 102,216, Nov. 12, 1915. (Appl. No. 6665 of 1916.)

NITROSULPHONIC acid is used in place of concentrated sulphuric acid to absorb the water formed during the nitration of aromatic compounds with nitric acid. *Example*: 50 grms. of *m*-dinitrobenzene is slowly heated with 100 grms. of nitrosulphonic acid until dissolved, 100 grms. of nitric acid is added to the solution, and the mixture is maintained at 100–120° C. until *s*-trinitrobenzene is formed.—F. W. A.

Amines ; Producing aromatic—, and *catalysts therefor*. O. Schmidt, Assignor to Badische Anilin und Soda Fabr., Ludwigshafen, Germany. U.S. Pat. 1,207,802, Dec. 12, 1916. Date of appl., Oct. 21, 1914.

SEE Ger. Pat. 282,568 of 1913; this J., 1915, 708. The hydrogen may be mixed with carbon monoxide, and a zinc compound may be used to promote the action of the copper catalyst.

IV.—COLOURING MATTERS AND DYES.

Sulphonaphthalin series of indicators and the quinone-phenolate theory. Lubs and Acree. See XXIII.

PATENTS.

Dyestuffs ; Manufacture of aniline—, D. de Nagy, A. E. King, and G. H. Odell, London. Eng. Pat. 16,203, Nov. 17, 1915.

DYESTUFFS are produced in substance or on the fibre by the oxidation of aromatic amines by using molybdates instead of salts of copper, iron, arsenic, and vanadium. *Examples*: (A) 5 grms. of hydrochloric acid (18° B.; sp.gr. 1.143), 5 grms. of aniline, 1 gm. of *p*-nitraniline, 2 grms. of nitrobenzene, and 0.03 gm. of ammonium molybdate are boiled together, and the temperature raised to 220–230° C. until the mass forms a paste; this paste is dissolved in hot water and the red dyestuff precipitated with soda; it may be dyed from an acetic acid bath. (B) Black or black-blue shades are produced on the fibre by padding unmercerized silk, wool, or cotton with the following mixture at 70° C.: 5 grms. of *o*- or *p*-chloroaniline, 25 grms. of hydrochloric acid (18° B.; sp.gr. 1.143), 0.02 gm. of ammonium molybdate, 0.5 gm. of diphenylamine, 5 grms. of potassium bichromate, and 1.8 grms. of potassium chlorate dissolved in 1 litre of water; the material is subsequently immersed in dilute caustic soda.—F. W. A.

**o*-(Hydroxyazo dyestuffs sensitive to metals ; Manufacture of metal compounds of — and their application in dyeing animal and vegetable fibres.* O. Huray, London. From Society of Chemical Industry in Basle, Switzerland. Eng. Pat. 16,803, Nov. 29, 1915.

WATER-SOLUBLE compounds of *o*-hydroxyazo dyestuffs with nickel, cobalt, iron, aluminium, vanadium, and uranium, similar to the copper compounds described in Eng. Pats. 1611, 12,249, and 15,127 of 1915 (this J., 1916, 301, 922, 1104) in that they are no longer sensitive to metals, have been isolated. When dyed in an acid bath they give tints which are different from those obtained from ordinary salts of the dyestuff acids. They may also be applied according to the various processes in use for chrome mordant dyestuffs, giving shades of greater fastness to milling and to potting.—F. W. A.

**o*-Hydroxyazo dyestuffs and metal compounds thereof ; Manufacture of — and their application in dyeing.* O. Huray, London. From Society of Chemical Industry in Basle, Switzerland. Eng. Pat. 16,916, Dec. 1, 1915.

ORANGE to red azo dyestuffs, which on after-chroming become fast to milling, light, and potting, are obtained by combining diazotised *o*-amino-phenol or -naphthol or a derivative with a pyrazolone derivative of the benzene or naphthalene series containing a hydroxyl group in the aromatic nucleus, other than the pyrazolone from 2,5-aminonaphthol-7-sulphonic acid (see Eng. Pats. 12,250 and 12,932 of 1915; this J., 1916, 1008). The copper, chromium, iron, cobalt, nickel, aluminium, etc., compounds are obtained by the action of a metallic salt on an aqueous solution or suspension of the dyestuff, or by producing the dyestuff in presence of the metallic salt. Instead of using the after-chrome process, the dyestuffs may be dyed on chrome-mordanted wool or by the metachrome process.—F. W. A.

Azo dyestuffs and process of producing the same. A. L. Laska, Offenbach, Assignor to Chem. Fabr. Griesheim-Elkhron, Frankfurt, Germany. U.S. Pat. 1,206,232, Nov. 28, 1916. Date of appl., Feb. 25, 1916.

DIAZO compounds of asymmetrically alkylated *p*-diaminoazo compounds are combined with arylides of 2,3-hydroxynaphthoic acid. (See also Eng. Pat. 100,804 of 1916; this J., 1916, 888.) —F. W. A.

*Finely divided pigment dyestuffs of the *N*-dihydro-1,2,2'-indanthraquinone series ; Production of —.* Farb- u. vorm. Meister, Lucius, und Brüning, Ger. Pat. 294,530, Feb. 3, 1914.

By oxidation of the leuco-Indanthrene precipitated by acidifying an Indanthrene vat, Indanthrene is obtained in a very finely divided form suitable for the production of pigments.—F. W. A.

Azo-dyestuff [from 1-aminoanthraquinone] ; Manufacture of an insoluble—, Badische Anilin und Soda Fabrik. Ger. Pat. 295,025, Nov. 20, 1914.

DIAZOTISED 1-aminoanthraquinone is coupled with ethyl acetoacetate in presence or absence of substrata. A pure yellow dyestuff is obtained suitable for the manufacture of lakes on account of its insolubility in water, oil, and alcohol and its great fastness to light.—F. W. A.

Anthraquinone dyes and process of making them. H. Neresheimer, Assignor to Badische Anilin und Soda Fabr., Ludwigshafen, Germany. U.S. Pat. 1,207,981, Dec. 12, 1916. Date of appl., Oct. 29, 1914.

SEE Ger. Pat. 287,614 of 1914; this J., 1916, 171.

Anthraquinone dyes and process of making them. H. Neresheimer, Assignor to Badische Anilin und Soda Fabr., Ludwigshafen, Germany. U.S. Pat. 1,207,982, Dec. 12, 1916. Date of appl., Oct. 29, 1914.

SEE Eng. Pat. 17,764 of 1914; this J., 1916, 831.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Wool ; Chemical method of detecting deterioration of—, O. Sauer. Z. angew. Chem., 1916, 29, 421.

AN attempt to evaluate wool from a chemical standpoint was made, based on a determination of the proportion of the total nitrogen which it

yielded to solvents. The procedure consisted in treating 0.5 gm. of wool with 40 c.c. of water, 50 c.c. of 1% hydrogen peroxide solution, and 40 c.c. of $N/2$ potassium hydroxide for three days, after which the nitrogen in an aliquot portion of the solution was determined and thence the total dissolved nitrogen calculated as a percentage of the nitrogen content of the original wool. In wool that had been exposed for four months to sunlight, a much higher proportion (45–50%) of the total nitrogen was soluble than in non-illuminated specimens (11–13%). In the case of dyed wool this change due to light, though still noticeable, was greatly retarded.—G. F. M.

Textile plants; Industrial retting of — by microbiological action. G. Rossi. Bull. Agric. Intell., 1916, 8, 1067–1074.

THE retting of textile materials by the action of pure cultures of specific pectic bacteria, particularly *B. comesii*, offers great advantages over the ordinary methods of field retting and over all chemical retting processes, in that the destruction of the pectic matters may be carried out completely without any action on the cellulose fibre. Sterilised leaves or wisps of hemp treated with this bacillus are completely resolved into parenchyma cells, sclerenchyma skeleton, and epidermis, and the separated elements may be kept in presence of the living bacteria under aseptic conditions for two years without breaking up or weakening the fibre structure. In the industrial application of the process, sterilisation of the media is not practicable; the materials are steeped in ordinary water at 28°–35° C., which is the most favourable temperature for the fermentation, a sufficient quantity of a pure culture of the bacillus is added, and the mass is artificially aerated during the entire period of retting. The aeration regularises and intensifies the action of the aerobic pectic ferments and suppresses the development of foreign organisms inimical to the cellulose. The treatment of hemp may be effected either on the entire plant or on the material after scutching in the green state in the field or at the factory. The latter method, if the scutching be properly carried out, presents many advantages: the weight and bulk of the material to be treated are very considerably reduced and retting operations on the dry scutched material may be carried on all the year round under industrial conditions. Green scutching is a somewhat delicate operation because a particular machine is not equally suitable for all kinds of hemp, and the results are less favourable the greater the percentage of moisture and the finer the stalks; nevertheless it is possible to find suitable scutchers which reduce the weight of stalk by 38–61%, according to the quality of hemp, without producing abnormal quantities of tow. The fibre retted after scutching and drying is smoother, less divided, and more glossy than ordinary hemp fibre, and the strips appear to adhere, but a slight brushing process suffices to impart an excellent degree of flexibility, division, and colour. A factory has been working in France equipped for the conveyance of hemp stalks from the fields, trimming, drying, and scutching the stalks, comprising also a retting department containing 4 vats of 19.62 cub. yds. capacity each, which are further sub-divided, a pure culture department for the production of ferments, and plant for washing, draining, and drying the fibre. The retting of the hemp is regularly completed in 48 hours. The application of the method to flax is precisely similar. In the case of ramie, the method shows great promise, but is only practicable commercially in the case of the decorticated strips known as China grass. The product is different from the ramie fibre prepared by chemical means and in many respects superior.—J. F. B.

Kapok fibre; Characteristics and basis of valuation of —. C. F. Cross and E. J. Bevan. J. Soc. Dyers and Col., 1916, 32, 274–278.

THE true kapok is the seed hair of *Eriodendron anfractuosum*, but commercially other vegetable down has been classed under the same name. The most important use for kapok at the present time is as a stuffing for appliances for saving life at sea and its value depends primarily on its property of resisting the penetration of water for a considerable length of time. This property is not due to the presence of specific water-repellent substances, as the total content of oil, wax, and resin is comprised between the limits of 0.5–1.8%, but is attributable to the peculiar structure of the fibre as a thin-walled tube enclosing a relatively large volume of air. When distilled with hydrochloric acid, kapok fibre yields from 12.3 to 17.4% of furfural, the lower qualities giving the higher yields. The "furfureoids" or pentosans are readily hydrolysable and are not re-precipitated with the more resistant fibre-substance after dissolving in 73% sulphuric acid. From an examination of the seed residues it would appear that commercial specimens of lower value, giving high percentages of furfural, were derived from some species of *Asclepiad* and not from the true kapok; a range of seven samples was examined representing values from 34d. to 8d. per lb. When these were classified according to the diameters of the fibres, taking the ratio of the extreme dimensions, this showed remarkable uniformity (ratio of extremes 1:2.0), in the case of the best qualities, average 0.021 mm., and great variability (ratio 1:6.2) in the lowest qualities average 0.028 mm., accompanied by considerable flattening and weakening of the cell walls. When the fibre is immersed in a hydrocarbon liquid to displace the interstitial air, the air within the tubes is not expelled, and the apparent specific gravity thus determined is a valuable criterion of quality, ranging from 0.407 for the best to 0.686 for the lowest grade. The cell wall represents on the average about one-fifth of the total diameter of the fibre. "Sinking" tests with water take an inconvenient length of time but aqueous alcohol, sp. gr. 0.928, penetrates more rapidly, and tests with this liquid may be carried out so as to indicate the inferior grades within a reasonable time. The phloroglucinol test shows little or no coloration with the higher grades of kapok but a marked reaction with the lower qualities. Length and uniformity of staple, freedom from seed residues, and a careful comparison with authentic samples are additional factors in the commercial valuation. In the life-saving appliances, the kapok stuffing occupies about 15 c.c. per gm. of fibre and the jacket contains 700 grms. of stuffing, representing a floating power of 10.5 kilos. After 72 hours in water, with a weight of 9 kilos. attached, this jacket still required 1.3 kilos. more to submerge it, and after 192 hours the weight required was 0.9 kilo.—J. F. B.

PATENTS.

Wool or other fibrous material; Apparatus for drying —. H. Walker, Cleckheaton, Yorks. Eng. Pat. 102,391, Jan. 19, 1916. (Appl. No. 851 of 1916.)

IN a cylinder drying machine in which the material is passed in the form of a sheet of sliver around a series of superposed perforated rotating cylinders, arranged in staggered relationship to each other, in a drying chamber, hot air being forced into the cylinders and through the perforations, the material is carried by two endless aprons or sets of tapes over and under the consecutive cylinders and supported by guide rolls within the drying chambers. The aprons or tapes pass round a pair of feed rolls at one end of the machine and delivery rolls at the

other. (Reference is directed under Sect. 7, Subsect. 4, of the Patents and Designs Act, 1907, to Eng. Pat. 10,806 of 1886.)—J. F. B.

Textile fabrics for the manufacture of bills, coverings, containers, and the like: Process for treating —. E. C. R. Marks, London. From Aktieselskabet Drivremmfabriken "Dana," Copenhagen. Eng. Pat. 16,985, Dec. 2, 1915.

SEVERAL webs of textile fabric are treated separately in a bath of sulphuric acid of such a strength that the surface of the material is converted into an adhesive mass resembling amyloid. The treated webs are superposed and united by pressure while still moist, and the residual acid is removed by washing first in a rapidly flowing stream of water and subsequently by steeping in a bath of water containing a neutralising agent. —J. F. B.

Resinous woods: Process of treating —. H. C. Alford, Assignor to J. M. Walsh and B. Thurley, Mobile, Ala., and H. C. Alford, Baldwin Co., Ala. U.S. Pat. 1,206,283, Nov. 28, 1916. Date of appl., July 11, 1911.

A CHARGE of wood particles confined in a series of intercommunicating containers is subjected to the action of a hot resin solvent which is passed through the series under pneumatic pressure, the temperature of the solvent increasing progressively through the series; when the charge in the first container becomes exhausted it is cut out and a freshly charged container is substituted at the other end of the series. The solution of resin is distilled and the solvent recovered for further use. The residual wood is steamed until free from solvent, then converted into pulp by treatment with caustic soda. Caustic soda is regenerated from the spent solution by treatment with an oxide or hydroxide of an alkaline earth.—J. F. B.

Vegetable fibres: Process of treating — [for the manufacture of paper pulp]. H. G. Green, Chicago, Ill. U.S. Pat. 1,206,777, Nov. 28, 1916. Date of appl., Sept. 17, 1913; renewed Apr. 24, 1916.

IN the manufacture of paper pulp, the material is broken up to loosen the woody portion from the fibre proper, part of the woody portion is removed, and the residue is moistened with about 70% of its weight of water, treated with chlorine gas at the ordinary temperature, and boiled in a suitable solution to disintegrate the remaining woody matter.—J. F. B.

Wool and like washing machines. F. B. Petrie, Rochdale. U.S. Pat. 1,207,207, Dec. 5, 1916. Date of appl., Nov. 23, 1915.

SEE Eng. Pat. 22,838 of 1914; this J., 1916, 172.

Leather; Manufacture of a product analogous to — [from *lex tles*]. Aktieselskabet Drivremmfabriken "Dana." Fr. Pat. 480,433, Dec. 11, 1915.

SEE Eng. Pat. 16,985 of 1915; preceding.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Resorcinol: Application of — in dyeing and printing with the basic colours. A. Wosnessensky. J. Soc. Dyers and Col., 1916, 32, 278—280.

RESORCINOL in combination with formaldehyde has been proposed as a mordant for basic dyestuffs in substitution for the usual tannin mordant, but the results were not commercially favourable. The author has employed resorcinol as a solvent

for the lakes formed by tannin with the basic dyestuffs, whereby these colours may be applied by the "single bath" process and by the padding machine. For this purpose, resorcinol is a far more efficient and satisfactory solvent than certain others which have been proposed, e.g., various alcohols, phenol, and acids, and its action is continued in the steaming bath, where other solvents are volatilised. A process was described in Eng. Pat. 9052 of 1914 (this J., 1915, 901) in which 30 parts of basic dyestuff, 50 of resorcinol, 80 of tannin, and 200 of acetic acid are dissolved, diluted with hot water to 1 litre, and the goods padded with this solution, steamed, and passed through an antimony bath. The superiority of the effects obtained is attributed to the better penetration which takes place during the steaming. A process of printing with basic dyestuffs, whereby the passage through a separate bath of antimony salt is avoided, has also been described. The paste consists of basic dyestuff, resorcinol, tartaric acid, tannin, tartar emetic, and a tragacanth thickening; after printing, the goods are merely steamed and rinsed. The fastness is as satisfactory as in the ordinary method of printing, and the "whites" are clearer. The omission of the separate antimony bath is of special advantage when printing basic dyestuffs in conjunction with other dyestuffs. Another use for resorcinol is for dissolving the tannin lakes in discharge colours containing basic dyestuffs.—J. F. B.

Biological valuation of the so-called "solivines" (Turkey-red oils). Kobert and Greuel. See XII.

Theory of vegetable tanning. Procter and Wilson. See XV.

PATENTS.

Foam in the degreasing, soaping, mordanting, dyeing, degumming or other treatment of raw or finished textile materials: Process for producing —. R. Clavel, Basle, Switzerland. Eng. Pat. 102,310, Mar. 23, 1916. (Appl. No. 4316 of 1916.)

IN treating raw or finished textiles with foam, instead of producing the foam by boiling suitable solutions into which air may be introduced, or at lower temperatures by reducing the pressure, air, oxygen, or other oxidising, reducing, or indifferent gas is introduced under pressure through finely porous bodies such as tubes or plates of unglazed earthenware, agglomerated powdered graphite, or the like. For degumming silk the operation is carried out at 75°–95°C., and the action is accelerated by using an oxidising gas such as oxygen or air.—F. W. A.

Mordants on silk fibres or tissues; Fixing iron —. Gebr. Schmid, Basle, Switzerland. Eng. Pat. 102,331, May 30, 1916. (Appl. No. 7664 of 1916.) Under Int. Conv., Jan. 25, 1916.

SILKWORM chrysalides or silk-waste containing chrysalides, or the oily water obtained by boiling silk-worm chrysalides or waste containing chrysalides, may be used to replace entirely or in part the soap usually added to the bath used to fix iron mordants on silk fibres or tissues.—F. W. A.

Acid colours on cotton; Fixation of —. Know Mill Printing Co., Ltd., Manchester, and F. W. Weeks, Edgworth. Eng. Pat. 102,291, Feb. 15, 1916. (Appl. No. 2228 of 1916.)

SHADES fast to boiling and to soaping are obtained in dyeing and printing cotton goods with acid dyestuffs by using as fixing agents the condensation products formed by the interaction of aromatic amines and aldehydes or their chemical equivalents, for example, aniline salt and hexamethylenetetramine.—F. W. A.

Dyeings similar to Turkey-red; Production of fast —. Farbw. vorm. Meister, Lucius, und Brüning. Ger. Pat. 294,780, Mar. 20, 1914.

AROMATIC diazo compounds are coupled, on the fibre, with 2,3-hydroxynaphthylaminothiazole, its homologues or analogues, or their substitution products. A bright, very fast red is obtained in this way from diazotised *p*-nitro-*o*-toluidine.—A. S.

Azo dyestuffs on the fibre; Production of —. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 294,798, Nov. 26, 1914.

THE arylides of 6-hydroxy-2-naphthol-3-carboxylic acid dissolve readily in dilute sodium carbonate solution on warming. The fibre is impregnated with such a solution and then treated with a solution of an unsulphonated diazo compound. Clear red to dark blue shades of excellent fastness are produced on unmordanted cotton.—A. S.

Black shades on wool; Production of —. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 294,931, Dec. 9, 1915. Addition to Ger. Pat. 291,021.

SHADES fast to potting as well as to milling are obtained by using the sulphonic acids of *symms.*-di- β -naphthyl-4,4'-diaminodiphenylamine or its substitution products instead of the substances mentioned in the chief patent (this J., 1916, 834). —A. S.

Plants; Process for dyeing, in brown or black shades, parts of — containing tannin. A. Wieler, Aachen. Ger. Pat. 294,833, Jan. 15, 1916.

PARTS of plants containing tannin are treated with ammonia or with ammonium compounds, phenols, or pyridine bases, in the form of vapour, in order to convert the tannin into coloured insoluble compounds.—A. S.

Sizing and dyeing; Composition of matter for —. Composition of matter and method of making the same. M. N. Aisen, Chicago, Ill. U.S. Pats. (A) 1,206,189 and (B) 1,206,190, Nov. 28, 1916. Dates of appl., May 15, and July 6, 1914.

(A) HYDROLYSED glue in alcoholic solution is mixed with a basic dyestuff for sizing and dyeing. (B) Glue is hydrolysed by means of an alkali and dissolved in an organic solvent.—B. N.

Dressing for hats. W. Philippsthal, Berlin-Grünwald. Ger. Pat. 294,730, Feb. 26, 1916.

WATER-GLASS is used, with addition of glue, gelatin, flour, gum-tragacanth, Iceland moss, etc.—A. S.

Weighting silk with hamatoxylin; Process of —. F. Mueller, Zürich, Switzerland. U.S. Pat. 1,207,784, Dec. 12, 1916. Date of appl., Nov. 29, 1913. SEE Eng. Pat. 26,735 of 1913; this J., 1914, 418.

Weighting silk; Process for —. P. Schmid and K. Gross, Basle, Switzerland. U.S. Pat. 1,207,800, Dec. 12, 1916. Date of appl., Oct. 7, 1915. SEE Ger. Pat. 287,754 of 1914; this J., 1916, 171.

Manufacture of aniline dyestuffs. Eng. Pat. 16,203. See IV.

Manufacture of metal compounds of o-hydroxyazo dyestuffs sensitive to metals and their application in dyeing animal and vegetable fibres. Eng. Pat. 16,803. See IV.

Manufacture of o-hydroxyazo dyestuffs and metal compounds thereof, and their application in dyeing. Eng. Pat. 16,916. See IV.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Sulphuric acid manufacture by the contact process; Substitutes for platinum in —. Fahrenwaldt Bull. Amer. Inst. Min. Eng. Chem. Trade J., Jan. 6, 1917.

EXPERIMENTS carried out in Germany have shown that compounds of silver and vanadium can be used in place of platinum in the contact process of sulphuric acid manufacture. The author has found that other efficient substitutes for platinum are alloys of palladium with silver or gold, and also pure tungsten and to a certain extent molybdenum. Tungsten and molybdenum, however, are easily oxidised, but alloys of these metals with precious metals are even more efficient than platinum and its alloys, such as platinum-iridium.

Sulphurous acid; Electrolytic oxidation of —. M. de K. and N. J. Thompson. Met. and Chem. Eng., 1916, 15, 677—679.

THE authors used as diaphragm an earthenware cup containing a cylindrical nickel cathode with a cylindrical platinum gauze anode surrounding the diaphragm, the porous cup being filled either with sulphuric acid or sodium sulphite. Outside the cup was a solution of sulphur dioxide of 1 to 5% concentration; the anode solution was kept saturated during electrolysis by passing in a current of sulphur dioxide. The current density was about 0.0075 ampère per sq. cm. Results proved that sulphurous acid is easily oxidised at platinum anodes to sulphuric acid of any concentration below 95%. The concentration of sulphuric acid in the cell has a great effect on the current efficiency, as also has the current density but in a lesser degree. Oxidation takes place with high current efficiencies even in strong sulphuric acid solutions. For a given sulphuric acid concentration the current efficiency decreases with increasing current density.—T. H. B.

Formic acid; Catalytic decomposition of — by rhodium. P. C. Haas. Z. Elektrochem., 1916, 22, 443—445.

IT has been previously stated (Bredig and Blackadder, this J., 1913, 21) that the decomposition of formic acid into hydrogen and carbon dioxide by contact with rhodium is only brought about when this metal has been activated by the presence of occluded oxygen or traces of sulphur which act as depolarisers. This catalytic action can be closely imitated by electrolysis with platinum electrodes. By observing the decomposition voltage, a value is obtained which gives a measure of the tendency to decompose. The influence of catalysts and depolarisers on the decomposition can be determined quantitatively in this way. Measurements were made by the Le Blanc method, the potential difference between the electrode and surrounding electrolyte being plotted on a curve against the current. A sharp rise in the current on gradually increasing the voltage indicates the point of decomposition. With electrodes of platinumised platinum, a decomposition point could in some cases be observed with formic acid solutions at 0.18 volt. The presence of platinum black had a greater influence at the anode than at the cathode. Measurements were made with rhodium-plated platinum electrodes, but it was not possible to detect any difference in the decomposition voltages between active and non-active conditions of the metal.—J. N. P.

Ammonia; Catalytic oxidation of —. E. B. Andersen. Z. Elektrochem., 1916, 22, 441—443. THE oxidation of ammonia can be made to proceed in accordance with the equation:

$$4\text{NH}_3 + 7\text{O}_2 = 4\text{NO}_2 + 6\text{H}_2\text{O},$$

and the velocity of the reaction can be accelerated by means of suitable catalysts. The progress of the oxidation is also determined by the equilibrium condition obtained in the equation:

Since this reaction is exothermic, it follows that the higher the temperature, the greater is the quantity of ammonia that will remain unchanged when a state of equilibrium has been reached. However, in presence of excess of oxygen, this oxidation is practically quantitative within a large range of temperatures. On passing mixtures of air and ammonia containing from 2.5 to 5% NH_3 by volume, over a suitable catalyst at temperatures from 500° to 1000° abs., at a speed which ensured the mixture remaining in contact with the catalyst for a time varying from 0.18 to 1.15 seconds, the amount of ammonia converted to oxides of nitrogen was 98 per cent. The direct synthesis of nitric oxide from nitrogen and oxygen does not come into play in this reaction, as the equilibrium concentration of NO in the equation: $\text{N}_2 + \text{O}_2 = 2\text{NO}$ is only 0.0003% NO at 600 abs. Any catalyst which favours this synthesis, is unsuitable for the ammonia oxidation.—J. N. P.

Cape asbestos industry. G. E. B. Frood. *India-rubber J.* 1917, 53, 17—20.

IN a recently published Government report on mining in South Africa, a description of the occurrences of asbestos and of the product is given, together with an attempt to estimate the value of the blue asbestos for commercial purposes. The extent of the deposits in the Northern portion of Cape Colony is indicated, the three districts of Kuruman, Hay, and Prieska being mentioned as constituting the largest asbestos-bearing area in the world. The Cape Asbestos Company now possesses factories for milling and manufacturing the product in England, Turin, and Hamburg, whilst a sister company in Paris has been developed to control the interests of the company in France. The cheapness of working, due to native labour, is remarkable, as also the freedom from accident. The author suggests that all properties should be worked on an underground system from the start. The classification of the product based generally on the length of the fibre is discussed, it being understood that for textile purposes about 25% of the fibre must be 1 inch and over. Outside such purposes, there should be a good market, as in roofing material, in which the length of the fibre is less important. The whole Cape output of blue asbestos realises at present an average of about £25 a ton landed in England. Comparative analyses of blue asbestos and white asbestos (Canadian) are given. Blue asbestos possesses great heat-resisting properties, and is said to be unaffected by moisture, ordinary acids, chemical solutions, and particularly sea-water. The production of asbestos in various countries is given, indicating a remarkable increase in the figures for Cape Colony. With the assurance of a widening market the future progress is likely to be much more rapid.—J. E. C.

Zinc; Volumetric determination of — in its chloride, nitrate, and sulphate. F. W. Sjöström. *Farm. Revy*, 1916, 480—491. *Z. angew. Chem.*, 1916, 29, Ref., 511.

IN an alkaline solution of zinc chloride, nitrate, or sulphate, of known alkali content, be treated with excess of pure hydrogen peroxide solution, the zinc is precipitated quantitatively as zinc perhydroxide, and a certain quantity of alkali is neutralised by the liberated anion. The excess of alkali is titrated and the quantity of zinc calculated, allowance being made for any free acid present in the original zinc solution before making alkaline.—A. S.

Iron trisulphide [ferrie sulphide], and the formation of iron disulphide. V. Rodt. *Z. angew. Chem.*, 1916, 29, 422—423.

THE existence of ferrie sulphide, Fe_2S_3 , was confirmed and the contradictory statements found in the literature about this substance are explained by its instability when in a moist condition. It was obtained by the action of hydrogen sulphide on moist ferrie hydroxide. When dry it is comparatively stable except towards oxygen, but in presence of water and absence of air it decomposes almost entirely in the course of a week into a mixture of the mono- and di-sulphides: $\text{Fe}_2\text{S}_3 \rightarrow \text{FeS}_2 + \text{FeS}$. This change is arrested by the smallest trace of alkali. In presence of air moist ferrie sulphide is slowly oxidised to a hydrated ferrie oxide and free sulphur. The formation of iron disulphide was also observed as the result of the direct combination of ferrous sulphide and sulphur in aqueous suspension, even at ordinary temperatures, and the slow gradual addition of a solution of sodium polysulphide to a boiling ferrous sulphate solution, taking care that the mixture never became alkaline, resulted in the almost complete conversion of the iron into amorphous disulphide according to the equation: $\text{FeSO}_4 + \text{Na}_2\text{S}_3 = \text{FeS}_2 + \text{Na}_2\text{SO}_4 + \text{S}$. The amorphous iron pyrites often found in moorland soil, which is so deleterious to underground building work, has probably been formed by one or other of these precipitation methods.—G. F. M.

Iodine; Occurrence of — in German potassium salts. L. W. Winkler. *Z. angew. Chem.*, 1916, 29, 451—452. (See also this J., 1916, 1058.)

THE natural saline water from a potash deposit in Mecklenburg was found to contain 17 mgrms. iodine (as iodide) per litre, about 340 times as much as sea water contains. Iodine (0.5 mgrm. per litre) was also found in a sylvinite mother liquor from Alsace.—J. N. P.

Restrictions in use of magnesite. See VIII.

Solubility of calcium sulphite in water and in sugar solutions. Van der Linden. See XVII.

Stability of ammonium chlorate. Gelhaar. See XXII.

PATENTS.

Sulphuric acid; Manufacture of —. W. J. Alcock, Mill Hill, and G. K. Davis, Manchester. Eng. Pat. 16,981, Dec. 2, 1915.

WHEN ferrie oxide is used to convert sulphur dioxide into trioxide, the freedom from moisture of the air supply to the sulphur burners is essential. The sulphur, pyrites, or other sulphur-containing material is burnt in practically air-tight kilns, the gases from which pass first into a ferrie oxide column, afterwards into a Glover tower where a large proportion of the sulphur trioxide is absorbed. The acid from the Glover tower, when cooled, is brought into contact with the air to be used for combustion in the kilns, in special apparatus (see Eng. Pat. 17,005 of 1914; this J., 1915, 897). Any unconverted sulphur dioxide leaving the Glover tower is condensed in chambers connected with a Gay-Lussac tower.—T. H. B.

Sulphuric acid; Method of manufacturing —. A. M. Fairlie, Copperhill, Tenn. U.S. Pat. 1,205,723, Nov. 21, 1916. Date of appl., Feb. 25, 1915.

GASES free from nitrogen-oxygen compounds entering the acid-making system, and also those containing nitrogen-oxygen compounds at a pre-determined point in or near the Glover tower, where the percentage of sulphur dioxide is normally more than 0.7% by vol., are analysed, and by regulating the amounts of sulphur dioxide and of nitrogen-oxygen compounds introduced into the

system, the ratio between the percentages of sulphur dioxide in the gases at the two points is maintained at the value found best adapted to a commercially complete absorption of the nitrogen-oxygen compounds.—T. H. B.

Sulphur dioxide; Method of determining—A. M. Fairlie, Copperhill, Tenn. U.S. Pat. 1,205,724, Nov. 21, 1916. Date of appl., Feb. 23, 1916.

THE sulphur dioxide in gaseous mixtures, which may contain nitrogen-oxygen compounds, is determined by ascertaining the volume of the gas required to destroy the blue colour of a mixture of *N*/10 iodine solution, 1 c.c.; starch solution, 5–6 drops; saturated sodium acetate solution, 5 c.c.; strong acetic acid, about 5 c.c.; water, about 100 c.c.—T. H. B.

Gases [from sulphur or pyrites kilns]; Apparatus for cooling and purifying—H. B. P. Humphries, London, Eng. Pat. 17,232, Dec. 8, 1915.

AN outer shell is provided with an inner concentric shell depending from the cover and reaching nearly to the bottom of the outer shell. The annular space between the two shells contains a pipe coil for cooling fluid. Gases to be treated, e.g., gases from sulphur or pyrites kilns, are passed over the cooling coil and then up through the bottom of the inner shell which contains scrubbing and purifying material, to an outlet at the top.

—W. F. F.

Nitric acid and other products; Process of making—F. S. Washburn, New York. U.S. Pats. (A) 1,206,062 and (B) 1,206,063, Nov. 28, 1916. Dates of appl., Feb. 7, 1916, and May 6, 1916.

A) A MIXTURE of ammonia and oxygen-containing gases is subjected to a catalyst, at such a rate that free ammonia (not exceeding 20%) and nitrous gases appear in the products; a solution of nitric acid and ammonium nitrate is produced from the products, and this is concentrated and the nitric acid recovered. (B) The solution of nitric acid and ammonium nitrate, after concentration, is treated with sulphuric acid to concentrate the nitric acid and form ammonium sulphate.—T. H. B.

Sodium perborate; Manufacture of—Deutsche Gold- und Silber-Scheideanstalt, vorm. Roessler, Frankfurt, Germany. Eng. Pat. 100,153, Mar. 1, 1916. Under Int. Conv., Mar. 10, 1915. (Appl. No. 3127 of 1916.) (See this J., 1916, 1261.)

A SOLUTION containing a carbonate (13–15% anhydrous) and an alkali borate is electrolysed, the borate reacting with the percarbonate formed to produce perborate. It is essential that the solution be kept saturated with borax and that solid perborate be always present; and it is advisable that catalysts be absent. This may be effected either by using pure substances, or by adding such materials as alkali bicarbonate, stannic acid, or magnesium silicate (1–2 grms. per litre of electrolyte).—E. H. T.

Alkali perborates; Manufacture of—Deutsche Gold- und Silber-Scheideanstalt, vorm. Roessler, Frankfurt, Germany. Eng. Pat. 102,359, Aug. 8, 1916. Under Int. Conv., Mar. 17, 1916. (Appl. No. 11,185 of 1916.)

SODIUM perborate is made by electrolysing lyes containing soda and borax. The accumulation of bicarbonate, produced during the action, must be restricted to a maximum of 70–75 grms. per litre, otherwise the stability of the perborate would be affected adversely. Hence metaborate,

or free alkali and borax, are added during the electrolysis; or lime or other alkali is added to the waste lye prior to its treatment or re-treatment.

—E. H. T.

Silicon compound [for water softening] and process of making same. R. Boehringer, Newark, N.J., Assignor to Staten Island Chemical Corporation. U.S. Pat. 1,205,509, Nov. 21, 1916. Date of appl., Oct. 26, 1915.

A SILICON compound is produced by mixing a solution of an alkali silicate with a faintly alkaline solution of borax, and removing and drying the precipitate formed. The proportions and concentrations of solutions used are such as to form a compound which when dried and ground may be used as a filtering medium for the removal of calcium and magnesium from water.—T. H. B.

Magnesium compounds; Process of producing—S. Peacock, Philadelphia, Pa., Assignor to Marden, Orth and Hastings Co., Inc., New York. U.S. Pat. 1,205,659, Nov. 21, 1916. Date of appl., July 15, 1915.

MINERALS containing magnesium are finely powdered and treated with sulphuric acid, the heat of reaction being allowed to rise high enough to prevent formation of gelatinous silica; less sulphuric acid is used than is necessary to combine with all the magnesium. The magnesium compound thus produced is recovered.—T. H. B.

Nitrogen compounds; Synthetic production of—P. A. and E. A. Starke, Berkeley, Assignors to Standard Oil Co., Richmond, Cal. U.S. Pat. 1,206,155, Nov. 28, 1916. Date of appl., May 3, 1915.

CYANOGEN compounds are formed by passing a mixture of methane and air, heated to a temperature not lower than 600° C., through a catalyst consisting of a mixture of alkalis, or alkali and alkaline earths, with a metal of the iron group, and containing no carbon.—B. V. S.

Ammonia and compounds thereof; Manufacture of—H. W. Lamb, Portsmouth, Va. U.S. Pat. 1,207,567, Dec. 5, 1916. Date of appl., Sept. 17, 1913.

A METALLIC carbide, or a substance containing calcium carbide, is heated and exposed to the alternating action of nitrogen and hydrogen under pressure, the temperature being raised and lowered alternately.—E. H. T.

Ammonia generator. C. W. Vogt, Louisville, Ky. U.S. Pat. 1,208,242, Dec. 12, 1916. Date of appl., Oct. 15, 1915.

A CLOSED, horizontal, cylindrical shell contains a liquor chamber, an ammonia chamber, and a steam chamber nearly filled with a series of tubes which are closed at one end and communicate with the ammonia chamber at the other. Each tube is fitted with an inner tube which extends through the ammonia chamber into the liquor chamber. That part of the shell in which the tubes are situated is provided with a steam-inlet and a condenser-outlet; strong liquor is supplied to the liquor chamber, and weak liquor is drawn off from the ammonia chamber, the latter being also provided with an exit for ammonia gas.

—E. H. T.

Nitrogen compounds [from distillers' spent wash]; Manufacture of—E. Kochenderfer, Frankfurt, Germany. U.S. Pat. 1,207,416, Dec. 5, 1916. Date of appl., Mar. 26, 1913.

DISTILLERS' spent wash, or similar nitrogenous

matter, is carbonised and the gases evolved are passed through a superheater. The period of contact of the gases with the superheating surface is controlled by varying the ratio between the area of that surface and the speed of the gases, and the speed is adjusted according to the composition of the gases.—E. H. T.

Titanium oxide; Method of obtaining —, L. E. Barton, Niagara Falls, Assignor to The Titanium Alloy Manufacturing Co., New York, U.S. Pats. (A) 1,206,796, (B) 1,206,797, and (C) 1,206,798, Dec. 5, 1916. Date of appl., Mar. 7, 1916.

(A) MATERIAL containing titanic and iron oxides is heated either with an alkali sulphide, or with a carbonaceous substance and an alkali sulphate, to a temperature below the melting point of the charge, but sufficiently high to effect the formation of ferro-sodium sulphide and alkali titanate. The sintered product is then treated with an acid liquid, suitably diluted, which dissolves out more of the iron than of the titanium compounds. In the initial stage, the titaniferous material may be mixed with melted nitre cake, and digested at 175–250° C. until the substances have interacted; the reducing agent is then added and the process continued as before. (B) The acid solvent employed is dilute sulphurous acid, which may be added as such, or produced by passing sulphur dioxide into a mixture of the sintered product and water. (C) The product of the interaction of the original material and alkali sulphide is poured in a molten state into a vertical mould. By controlling the rate of cooling, two separate layers are formed, the upper one containing most of the iron, and the lower one most of the titanium compounds. After solidification these layers are separated from the rest of the casting.—E. H. T.

Aluminium chloride residus [from oil refining]; Utilisation of —, A. McD. McAfee, New York, Assignor to Gulf Refining Co., Pittsburgh, Pa., U.S. Pat. 1,206,871, Dec. 5, 1916. Date of appl., Mar. 2, 1915.

To coke residues containing aluminium chloride, as obtained in oil refining, some of the same material which has been oxidised by roasting in a limited air supply, is added, and the mixture is fused and electrolysed, whereby the carbon in the residues is oxidised and metallic aluminium is obtained.—E. H. T.

Air; Separating the gases of —, Apparatus for the separation of the constituents of air, J. P. Place, Glen Ridge, N.J., Assignor to American Air-Liquefying Co., New York, U.S. Pats. (A) 1,205,177 and (B) 1,205,178, Nov. 21, 1916. Dates of appl., June 8 and 9, 1915.

(A) AFTER a preliminary compression and cooling, in which water and carbon dioxide are removed, the compressed air is further cooled in several stages, using as cooling agents the nitrogenous products of rectification, boiling liquid nitrous oxide, and finally liquid oxygen at atmospheric pressure. (B) An arrangement of condensers and receptacles suitable for the above process.—B. V. S.

Carbonic acid gas; Absorbent medium for —, J. Cadman, Edgbaston, U.S. Pat. 1,207,273, Dec. 5, 1916. Date of appl., July 17, 1914.

SEE Eng. Pat. 12,451 of 1911; this J., 1915, 228.

Oxides of nitrogen; Manufacture of —, C. Bosch, A. Mittasch, and C. Beck, Assignors to Badische Anilin und Soda Fabr., Ludwigshafen, Germany, U.S. Pats. 1,207,706, 1,207,707, and 1,207,708, Dec. 12, 1916. Date of appl., Feb. 25, 1915.

SEE Eng. Pat. 13,818 of 1911; this J., 1915, 799.

Hydrosulphites; Production of anhydrous — from aqueous hydrosulphite solutions, E. Marburg and G. Münch, Assignors to Chem. Fabr. Griesheim-Elektron, Frankfurt, Germany, U.S. Pat. 1,207,782, Dec. 12, 1916. Date of appl., June 9, 1911.

SEE Ger. Pat. 279,389 of 1913; this J., 1915, 355.

Carbon monoxide; Process of absorbing —, W. Meiser and C. Krauch, Assignors to Badische Anilin u. Soda Fabr., Ludwigshafen, Germany, U.S. Pat. 1,207,968, Dec. 12, 1916. Date of appl., Feb. 25, 1915.

SEE Eng. Pat. 9271 of 1914; this J., 1915, 861.

VIII.—GLASS; CERAMICS.

Chemical and medical glass, etc. Regulations for trading.

THE Minister of Munitions has ordered, under date 2nd January, that all persons engaged in the manufacture, purchase, sale or other dealings in chemical and medical glass or glass tubing and rod shall comply with the following regulations:—

(1) No person shall manufacture any chemical or medical glass or glass tubing or rod unless the purpose for which the glass is required has been approved. Such approval must be evidenced by one or other of the following which must be quoted by the ordering firm together with the purpose for which the glass is required:—

(a) Reference to and number of an Admiralty, War Office or Ministry of Munitions contract for which the glass is necessary, or

(b) A certificate authorising the supply issued on behalf of the Minister of Munitions by the Director of Optical and Glassware Munitions.

(2) Manufacturers are required to render to the Director of Optical and Glassware Munitions, at regular intervals, full and accurate returns of their manufacture and output of chemical and medical glass and glass tubing and rod in accordance with the directions from time to time given by the said Director.

(3) No person shall buy, sell, or deal in any chemical or medical glass or glass tubing or rod situated or to be manufactured outside the United Kingdom unless a certificate authorising such purchase, sale or dealing has been issued on behalf of the Minister of Munitions by the Director of Optical and Glassware Munitions.

(4) For the purpose of this Order chemical and medical glass shall include resistance, chemical and bacteriological glassware, carbons, thermometers, glass for miners' safety flame lamps, glass for X-ray apparatus, hospital glassware and glass vessels (graduated or otherwise) manufactured for the purpose of containing reagents, drugs, medicines, pharmaceutical or biological substances or preparations; and glass tubing and rod shall include all glass tubing and glass rod made by the process of drawing.

(5) All applications in reference to the above Order should be made to the Director of Optical and Glassware Munitions, Ministry of Munitions of War, 117, Piccadilly, London, W.

NOTE.—Certificates will be granted to dealers to order reasonable quantities of chemical and medical glass and glass tubing and rod for the purpose of stock and/or export, provided that such orders are not considered by the Minister of Munitions as likely to interfere with the execution

of orders required for war purposes. No further authorisation to dispose of such stocks will be required, provided that in the case of articles, the export of which is prohibited, the usual permit to export be obtained.

Magnesite and magnesite products. Restrictions on use.

THE Minister of Munitions has prohibited, as from 10th January, the use of magnesite and magnesite products for or in connection with (a) the construction or repair of any building (other than a furnace) or any flooring or deck, or (b) the manufacture of any insulating or non-conducting material, except under and in accordance with the terms of a permit granted by the Minister of Munitions. All applications in reference to this order should be addressed to the Director of Steel Production (W.J.J. 342), Armament Buildings, Whitehall Place, London, S.W.

Zirconia objects; Preparation of —. O. Ruff and G. Lauschke. *Z. anorg. Chem.*, 1916, 97, 73—112. *Z. angew. Chem.*, 1916, 29, Ref., 503—501. (See also this J., 1914, 593, 647.)

By addition of small quantities of other oxides, zirconia objects can be made which, after burning in an exhausted carbon tube resistance furnace, in a reducing atmosphere, are sufficiently non-porous to be used in such a furnace. The most suitable additions are 1% of alumina for objects burnt at 2000° C., 1% of thorium for objects burnt at 2200° C., and 1—3% of yttria earths for objects burnt at 2400° C. Larger quantities of the oxides mentioned increase the porosity, as also do beryllium (glucinum) oxide and magnesia even when used in small quantities; silica also acts unfavourably. —A. S.

PATENTS.

Glass surfaces; Joining together —. F. Twyman, R. G. Parker, and A. J. Dalladay, Assignors to A. Hilger, Ltd., London. U.S. Pat. 1,206,177, Nov. 28, 1916. Date of appl., May 23, 1916.

A PROCESS of joining together glass surfaces without distortion consists in cleaning the surfaces, placing them in direct contact and then heating them sufficiently to cause them to unite firmly, yet without distortion. (See also Parker and Dalladay, this J., 1917, 32.)—A. B. S.

Transfers for earthenware, china, glass, and enamelled goods; Process for the production of —. L. Brindley, Burslem, Staffs. Eng. Pat. 15,142, Nov. 2, 1915.

THE designs are printed on tissue paper in one or more colours by means of engraved copper plates or rollers in the customary manner. The tissue paper is then applied, with the printed surface innermost, to the gummed surface of a sheet of duplex paper. A softening medium such as a mixture of linseed oil and oil of turpentine is applied to the tissue paper, which is then removed, leaving a perfect print on the duplex paper ready for application to the article to be decorated.—A. B. S.

Abrasive wheels; Process of making —. C. R. King, Assignor to Norton Co., Worcester, Mass. U.S. Pat. 1,208,330, Dec. 12, 1916. Date of appl., May 28, 1914.

A porous abrasive wheel is dipped in a cold solution of a synthetic resin and then heated so

as to transform the resin into a hard, tough, supplementary bond which will not be melted if the wheel becomes heated when in use.—A. B. S.

Carbon bricks and ceramic bodies containing carbon; Manufacture of —. Chem. Fabr. Dr. K. Albert, and L. Berend. Amöneburg. Ger. Pat. 291,661, Aug. 10, 1913.

CARBON, or a mixture of ceramic raw materials, is intimately mixed with an aqueous emulsion of an organic substance with an organic emulsifying agent, both of which yield finely divided carbon on carbonisation, and the mixture is heated until the constituents of the emulsion which are not volatilised are carbonised. Concentrated sulphite-cellulose waste lye is recommended as emulsifying agent, and tar, tar oils, or fatty oils, as substances to be emulsified. The raw mixture, before carbonising, may be used for lining furnaces, etc.—A. S.

Kiln or oven [for bricks]. U.S. Pat. 1,206,547. See IX.

IX.—BUILDING MATERIALS.

Concrete; Testing hardened —. F. Hart. *Chem.-Zeit.*, 1916, 40, 1032.

To ascertain the proportion of cement and sand in hardened concrete, it is necessary to examine the cement and aggregate from which the concrete was made. The sample of the roughly ground and air-dried concrete is further ground in a porcelain mortar until it will pass through a sieve with 120 holes per sq. cm. (It must not be too fine.) The aggregate is similarly treated and the cement is examined by the usual method. The loss on ignition, the proportion of matter insoluble in hydrochloric acid, the soluble silica, alumina, iron oxide, lime, magnesia, and sulphates are determined in the concrete, aggregate, and cement respectively, and the results are calculated to percentages on the calcined samples. Thus, if the aggregate consists of 96.20% insoluble residue and 3.80% soluble matter, and the concrete contains 80.27% insoluble matter, then the concrete contains $80.27 + 3.14$ (the corresponding quantity of soluble matter) = 83.41% aggregate and $100 - 83.41 = 16.56\%$ cement, and corresponds to a mixture of 1:5.04. When two different aggregates are used in the concrete, the probable proportions in which they have been mixed may be estimated in a similar manner. If the raw materials used for the concrete are not available, some of the particles of aggregate should be picked out of the crushed concrete and tested for calcium carbonate and other substances soluble in hydrochloric acid. If this is present, a further estimation of the amount of limestone, pumice, or clay ironstone present is impossible. If the aggregate is almost pure quartzose, the proportion present is calculated by assuming that the insoluble matter in the concrete is derived wholly from the aggregate and the soluble matter from the cement. As a check, the soluble ingredients should be compared with the analysis of normal Portland cement. If they agree, it is probable that the estimation of the composition of the concrete will be sufficiently correct; otherwise, it may be impossible to estimate the latter. If the manufacturer of the cement can be ascertained, it will usually be sufficiently accurate to obtain a sample of cement from him and to use this as the basis for calculation. In some cases, it is sufficient to substitute the analysis of an average cement. The estimation of the volumes of sand and cement used in the

manufacture of a given sample of hardened concrete is far less reliable than that of their percentages by weight.—A. B. S.

[Reinforced] concrete; *Cracking of—by salt water.* J. L. Harrison. Bull. Bureau of Public Works, Philippine Islands, Oct., 1916. Eng. and Min. J., 1916, 102, 1019–1020.

The cracking of numerous structures of reinforced concrete was traced to the presence of sodium chloride introduced by the use of brackish water or unwashed beach sand and gravel in the concrete mixture or by the use of salt water for wetting down the freshly set material. The failures were caused apparently by the bursting action of iron oxide formed in continuously increasing quantity around the embedded metal, this being rendered possible by the alternate production and decomposition of ferric chloride under the prevailing climatic conditions.—W. E. F. P.

Wood; *New method of fireproofing—* Engin. Rec., 1915, 72, 717. Bull. Agric. Intell., 1916, 8, 1166.

The following method of fireproofing shingles has been tested at the Forest Products Laboratory, Madison, Wis., U.S.A.:—The air-dry shingles are first impregnated with a solution of borax and dried in the stove until their moisture-content does not exceed 10%. Subsequently they are impregnated with a solution of zinc chloride, which forms a deposit of zinc borate in the pores, and again stove-dried. The zinc borate, being insoluble, resists exposure to running water and exerts a fireproofing effect by fusing at a high temperature and covering the wood fibres with a protective coating. The treatment can only be applied by means of a costly plant, including provision for impregnating the wood under high pressure, and consequently is only available on a large scale. In a fierce fire the treated shingles burn, but without flame, thus avoiding the danger of spreading the fire by falling sparks.—J. F. B.

PATENTS.

Refractory bricks and cement; Manufacture of— T. Twynan, Redcar. Eng. Pat. 102,386, Jan. 3, 1916. (Appl. No. 2 of 1916.)

MAGNESITE or dolomite is mixed with 3–5% of neutral slag wool preferably high in alumina, and then ground, or it may be ground dry in a ball mill and afterwards mixed with the slag wool and then made into bricks in the customary manner. Owing to the slag wool, the shrinkage of the bricks is very small and they remain true to shape. Bricks of lesser porosity are produced by adding 20–30% of highly shrunk magnesite to the ground mixture, or the porous bricks may be ground and then re-made into bricks. A mixture of magnesite or dolomite with 5–10% of slag wool makes a good cement for repairing the interior of metallurgical furnaces. The use of the slag wool avoids the necessity of burning the magnesite or dolomite at such high temperatures as are otherwise required. (Cf. Eng. Pats. 15,163 and 16,237 of 1915; this J., 1916, 1261.)—A. B. S.

Compositions for paving and building purposes. J. Gibb, Glasgow. Eng. Pat. 102,522, July 3, 1916. (Appl. No. 944 of 1916.)

SAWDUST free from large chips is soaked in water for 24 hours and mixed with at least half its volume of Portland cement and sufficient water to produce a consistency similar to that of mortar. Small stone chips or sand may be added if desired. The material may be moulded into blocks or laid

in situ. The product forms a durable, heat-resisting and resilient paving and building material of great strength and homogeneity and capable (when used for paving) of reducing skidding and slipping and of decreasing the noise of traffic. It is lighter than granolithic or concrete, yet equally durable; it does not "sweat," and nails can be driven into and held by it.—A. B. S.

Plastic binding composition; Process of preparing a— J. G. Vail, Chester, Pa. U.S. Pat. 1,206,656, Nov. 28, 1916. Date of appl., June 29, 1915.

AN emulsion of an alkaline solution of a silicate and a bituminous product is formed by equalising the viscosities of the substances and then mixing. The viscosity of the sodium silicate may be increased by incorporating stone screenings therewith; the viscosity of the bituminous product may be lessened with a suitable solvent.—T. H. B.

Building material; Artificial— and method of producing the same. L. Kern, Hamburg, Germany. U.S. Pat. 1,206,515, Nov. 28, 1916. Date of appl., June 22, 1914.

WET infusorial earth and fusible clay are mixed in such proportions that the product melts at 650°–950° C. The mixture is moulded and pressed into bricks, which are dried in a current of air, burned, and then cooled quickly. The bricks produced are porous, fireproof, and of low specific gravity.—A. B. S.

Diatomaceous earth; Process for producing articles from— L. Kern, Hamburg, Germany. U.S. Pat. 1,206,516, Nov. 28, 1916. Date of appl., May 15, 1915.

DIATOMACEOUS earth "and its compounds" are mixed with hydrochloric acid so as to convert any metallic compounds present into chloride, the product being moulded, partly dried, and then burned so as to convert the metallic chlorides into oxides.—A. B. S.

Kiln or oven [for bricks]. L. Kern, Hamburg, Germany. U.S. Pat. 1,206,517, Nov. 28, 1916. Date of appl., Jan. 4, 1916.

A TRIPLE stage vertical oven is provided with perforations in each of the three crowns, so that heat from a furnace in the lower part of the oven may rise vertically through it and pass out at the top. The lowermost stage forms the combustion chamber, the ones above contain the goods to be burned. Dampers are provided to divert some of the heat to the sides of the burning chambers.—A. B. S.

Furnace-lining material and process for preparing same. C. J. Barr, Birmingham, Ala., Assignor to A. S. Davison Co., Pittsburgh, Pa. U.S. Pat. 1,206,771, Nov. 28, 1916. Date of appl., Dec. 26, 1914.

GRAINS of non-fusible refractory material, such as dolomite, are roasted in a rotary kiln and a less refractory material, such as pulverised slag, is blown into the discharge end of the kiln, the temperature maintained at that end being such as will cause the pulverised material to fuse and coat separately the grains of dolomite with a non-cohesive envelope, so that when the product is formed into a granular lining of a furnace, the fusible coating serves to bind together the grains of refractory material to a permanent mass on exposure to the heat of the furnace.—J. F. B.

Building material; Manufacture of— T. Gürtler, Kleinzschachwitz. Ger. Pat. 295,013, Apr. 7, 1914.

BURNT clay, kaolin, or other material containing

alumina and silica, is mixed with a calcareous binding medium, and hardened by treatment with steam under pressure.—A. S.

Coating composition [for concrete]. U.S. Pat. 1,189,550. See XIII.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

German iron industry in 1915—1916. Z. angew. Chem., 1916, 29, Wirtschaftl. Teil, 697.

IN the period July 1, 1915, to June 30, 1916, the production of pig iron in Germany was 12,756,000 metric tons, as compared with 10,633,000 tons in 1914-15, an increase of 20%; the 1915-16 production amounted to 67% of that of 1913-14, the highest previously recorded. The steel production was 14,790,016 tons in 1915-16, as against 11,752,627 tons in 1914-15, an increase of 25.8%, and 82.6% of the highest production previously recorded. The total coal production was 87.8 million tons in 1915-16, as against 77 million tons in 1914-15, and the available supply, after deducting that consumed at the mines, was 68.4 and 60.6 million tons in 1915-16 and 1914-15 respectively. The amount of steel rolling mill products fell from 3,393,537 tons in 1914-15 to 3,279,632 tons in 1915-16. The year was a very profitable one for the companies concerned. In nearly all cases the profits were higher than any previously recorded—twice and in many cases three times as much as in the previous year. Dividends were increased and large sums were applied to writing off capital and providing special reserves in preparation for the severe competition anticipated after the war. The high profits were due largely to increased prices. Female labour and workers from occupied enemy territories have been used in an increasing degree during the past year.

Nickel in iron ores; Determination of—. P. Covitz. Met. and Chem. Eng., 1916, 15, 682—683.

THE following method, using dimethylglyoxime, is accurate and reasonably rapid, and the removal of other elements is not necessary. One grm. of finely powdered ore (100—120-mesh) is dissolved in 10 c.c. of nitric acid (sp.gr. 1.42) and 10 c.c. of hydrochloric acid (sp.gr. 1.2), quantities to be varied to suit the nature of the ore; sufficient nitric acid must be used to oxidise all reduced metals, particularly ferrous iron. After cooling, 10 c.c. of sulphuric acid (sp. gr. 1.81) is added, and the solution evaporated till copious white fumes appear. The nitric acid must be completely expelled or it will interfere in later stages. The solution is cooled, treated first with 30 c.c. of water, then with 2 to 3 c.c. of hydrochloric acid, heated for 10 to 15 minutes, and 5 grms. of citric or tartaric acid added. The solution is filtered, the filtrate diluted to 125 c.c., and neutralised with ammonia. If on passing the neutral point the solution is brown, enough citric acid is added to produce a green colour. After adding a few drops of hydrochloric acid to make barely acid, and heating to 70°—85° C., the nickel is precipitated by adding 20 c.c. of dimethylglyoxime reagent (8 grms. dimethylglyoxime in 1 litre ethyl alcohol); the solution is stirred constantly and allowed to boil. The precipitate is collected in a weighed Gooch crucible, and dried in an oven at 110° C. for 45 minutes; the dried precipitate contains 20.31% Ni.—T. H. B.

Cobalt ores; Occurrence and utilisation of—. Bull. Imp. Inst., 1916, 14, 417—437.

THE chief cobalt minerals are enumerated and particulars given of the distribution of cobalt ores throughout the world. In the Cobalt district of Ontario, Canada, the chief producing centre, cobalt and nickel occur in association with rich arsenical silver ore. During 1904—1914 the total production of cobalt in this district was 8007 tons, valued at £425,273; and, prior to the outbreak of war, sufficient ore was produced to provide over 1500 tons of cobalt oxide annually, the world's consumption of the oxide being then estimated at only 300 tons per annum. In the form of smalt, Thénard's and cerulian blues, Rinnmann's and turquoise greens, Indian yellow, cobalt brown, etc., cobalt compounds are employed as pigments, and in ceramics and other arts and industries, while the soluble salts form the basis of sympathetic inks. Until recent times metallic cobalt was not employed industrially to any extent, but the researches of Kahnus, instituted by the Canadian Department of Mines in 1912 and still in progress, have already resulted in a better knowledge of the properties and possible applications of the metal (see this J., 1914, 253, 261; 1915, 180, 619; 1916, 1113). Cobalt has been employed with success in the preparation of high speed steels, the latter containing 4% Co in addition to tungsten and chromium. Cobalt-chromium alloys of the "stellite" type (Co 75, Cr 25%) are much used for "stainless" cutlery on account of their hardness and resistance to acids; the hardness is further increased, and the alloys rendered suitable for high-speed tools, by the addition of tungsten and molybdenum. "Cochrome," an alloy similar to nichrome but containing cobalt instead of nickel, is in some respects superior to nichrome for electric heating elements, being less readily oxidised and having a higher melting point. Light alloys of aluminium and cobalt (Co 9—10%) have a coarsely crystalline structure and a tensile strength little more than that of aluminium; by the addition of 0.8—1.2% of tungsten or molybdenum the structure is refined and the strength increased to 2 or 3 times that of aluminium. Such alloys work and polish well, are very stable in air, and have a specific gravity between 2.8 and 2.9. An amalgam of cobalt is used in dentistry.—W. E. P. P.

Antimony ores; Occurrence and utilisation of—. Bull. Imp. Inst., 1916, 14, 389—417.

PARTICULARS are given of the occurrence of antimony ores throughout the world, together with statistics of imports into the United Kingdom during 1912—1915 and of the world's production of antimony ore and metal during 1911—1914. Prior to the war most of the antimony ore imported into this country came from Australia and China, whilst large quantities of crude antimony metal and regulus were imported from Mexico and China. Thus, in 1911, 2711 and 4367 tons of ore, valued at £38,704 and £33,911, were imported from Australia and China respectively, while 1294 and 1513 tons of crude antimony and regulus, valued at £21,857 and £46,500, were imported from China and Mexico respectively. During 1915 considerable amounts of ore, crude metal, and regulus were also imported from other countries, of which Algeria, Peru, Chile, Bolivia, Argentine Republic, Victoria, New South Wales, and Canada were the chief producers. The total imports of ore and of metal plus regulus in 1915 were 22,569 and 4691 tons, valued at £542,631 and £215,109 respectively; the corresponding figures for 1914 were 9179 and 3515 tons, valued at £90,760 and £85,371 respectively. For the production of metal for munition purposes, the

purchase of stibnite ores is conducted—by agreement with the Ministry of Munitions—on the basis of 11s. per unit per ton for an antimony content of 60% or over, 10s. 9d. for 55–60% Sb, and 10s. 6d. for 50–55% Sb; these gross prices are subject to a discount of 2½%, and the antimony content of an ore is calculated on the net dry weight received at the buyer's works, less a deduction of 12 lb. per ton draft. Ore containing less than 50% Sb is unsaleable under present circumstances if higher grade stibnite is available. Lead, bismuth, arsenic, copper, and zinc are considered objectionable impurities and penalised as follows. For each 0.1%, or part, of lead above 0.3 and up to 1.5% (the maximum permissible), a deduction of 5s. per ton is made; 7s. 6d. per ton is deducted for each 0.1%, or part, of arsenic or copper above 0.1 and up to 0.5%; if zinc or bismuth is present in more than traces the ore is subject to heavy deductions depending largely on the other constituents of the gangue. Siliceous ores are preferred to those of a pyritic character. Oxidised ores containing less than 50% Sb would probably be saleable, but the deductions from the price of 10s. 6d. per unit payable for 50% stibnite would be 1s. for each unit below 50 down to 45, and 2s. per unit below 45%. Brief descriptions are given of the concentration of stibnite ores by lixiviation, smelting by the English and the sublimation processes, and the refining of the crude metal, together with analyses of four brands of refined antimony. These latter contained 98.856–99.760% Sb, the impurities being Pb 0.402–0.718, Sn nil–0.012, As 0.090–0.210, Cu 0.012–0.016, Fe 0.004–0.007, Zn 0.023–0.034, Ni and Co nil–0.028, and S 0.078–0.201%. Metallic antimony as such has few uses; it is mainly employed industrially in the form of alloys, of which antifriction or "white" metal, type metal, hard lead, and Britannia metal are the chief types.—W. E. F. P.

Monazite and other thorium minerals in Ceylon; Recent work on —. Bull. Imp. Inst., 1916, 14, 321–369.

THE work of the Mineral Survey of Ceylon during 1911–1915, of which a summary is given, was devoted mainly to searching for thorium-bearing minerals on the west and south coasts and in various inland districts. Along the coast, most of which is bordered by shallow water, "nambu" — a natural concentrate of heavy minerals (mainly ilmenite and magnetite associated with monazite, garnet, zircon, rutile, etc.) varying from a film to several feet in thickness and from a foot to several yards in width — was found at many points. From Colombo to Dutch Bay Point and from Puttalam to Kudremalai the monazite content of these deposits was generally under 3%; but nambus containing 7, 9, and 12% respectively were found at the mouth of the Maha Oya, near Marawila, and near Welaboda, while a similar deposit near Kudremalai contained 22%. Between Colombo and Hambantota the nambus were black or red according as ilmenite or garnet predominated; although nearly always present in the former, monazite was seldom found in the latter. The nambu richest in monazite (17.5%) was found near Bentota; this material contained ThO₂ 4.15, Ce₂O₃, etc., 29.91, and U₃O₈ 0.18%, and on further concentration yielded a high-grade monazite sand comparing favourably with that now largely exported from Travancore and containing 9%–10% ThO₂. The alluvial deposits and gravels of the Ratnapura, Kelani Ganga, and Sitawaka Ganga districts were investigated by boring, etc., and although many of the samples were found to contain monazite, thorianite, gold, and gemstones the amounts were too small to permit of profitable extraction. On the Moon Plains in the Nuwara Eliya district, the source of a nambu rich

in monazite, xenotime, corundum, and zircon (the first two containing uranium) was traced to a pegmatite dyke the richer parts of which were found to contain 310 grms. of monazite per metric ton. An acid rock of the granulite type, containing a small proportion (20 grms. per ton) of monazite, was also found in this district; and it is considered probable that the granular monazite so widely distributed in the alluvial gravels of Ceylon is derived from similar rocks of the granulite series and not from the pegmatite intrusions. From a close examination of the Bambarabotuwa, Denawak Ganga, and Walawe Ganga districts, from which thorianite and thorite were formerly obtained as by-products in native gemming operations, it is concluded that the production can be renewed only by exploiting the thorianite-bearing lodes in these localities. Various thorianite-bearing veins at Niragama and Maddegama were investigated, and generally found to be unremunerative or unworkable under prevailing conditions; the Yalkumbura district was also prospected for thorium minerals with similar results.—W. E. F. P.

Use of pulverised fuel. Muhlfeld and Fuller. See 11A.

PATENTS.

Iron and steel; Method of changing the composition of —. B. Ford, Philadelphia, Pa. U.S. Pat. 1,205,611, Nov. 21, 1916. Date of appl. Aug. 3, 1909.

A mass of metal is melted and completely decarburised, and a second mass is "super-carburised to saturation," the masses being then mixed in predetermined quantities to give iron or steel of a definite carbon content.—B. N.

Iron ores; Preventing disintegration of — on smelting. "Phoenix" A.-G. für Bergbau und Hüttenbetrieb, Abt. Hoerder-Verein, Hoerde. Ger. Pat. 295,322, Mar. 11, 1916.

THE tendency of many iron ores, especially oolitic ores, to disintegrate when treated in the blast-furnace, etc., can be inhibited by slow drying of the ore, e.g., by heating, or by means of a current of warm air or gas; the heating may be continued until the combined hydrate-water is also removed.—A. S.

Furnaces; Crucible — and art of firing the same. J. and G. Keith, London. Eng. Pats. 17,902, Dec. 22, 1915, and 8793, June 22, 1916.

THE furnace, which has a stand for the crucible that can be raised or lowered, or an inner lining that can be raised or lowered, is heated by a mixture of gas and air which is preheated during its passage through a pipe placed in the waste gas flue. The gas burns from a number of tangential nozzles inclined upwards, which project into a circumferential channel of increasing cross-section at the upper part of the furnace; the hot products of combustion impinge on the cover of the furnace and are reverberated on to the crucible and pass down between the latter and the furnace liner to the waste gas flue below. The space between the furnace liner and the crucible is made as narrow as possible to economise fuel. To prevent overheating of the gas nozzles, the latter are thermally connected to the exterior wall of the furnace.—W. H. C.

Metals from liquids; [Electrolytic] process and apparatus for recovering —. C. E. Holland, New York. Assignor to Metals Electro-Recovery Co. U.S. Pat. 1,205,207, Nov. 21, 1916. Date of appl., Dec. 10, 1913.

THE liquid is passed from a tank into a receptacle,

open at the top, containing a series of plates near the bottom as electrodes, and an electric current is passed through the liquid, the current being intermittently reversed by a suitable pole changer. Hydrogen is liberated, and the minute particles of metal are carried by the gas to the top of the liquid, the flow of the latter also carrying the particles of suspended metal which have been released from the electrodes by the reversal of the current. The liquid overflows into a trough at the side of the tank and thence flows into a settling tank, in which the metal is separated, and the sediment is passed into a leaching tank. This is also in connection with a cyanide tank. The sediment is treated with cyanide solution, and the solution is passed into a recovery tank, provided with a series of anodes and cathodes in baffle formation, where it is subjected to electrolytic action. The slime is separated from the electrolytic deposit, and the liquid portion from the slime is returned to the cyanide tank for recovery of the cyanide solution.—B. N.

Ores and other products; Leaching——. J. E. Rothwell and H. B. Lowden, Assignors to Colorado Iron Works Co., Denver, Colo. U.S. Pat. 1,205,936, Nov. 21, 1916. Date of appl., June 3, 1912.

In a continuous leaching process a mixture of solids and solvent is agitated in a suitable vessel, a portion of the mixture being continuously withdrawn during agitation and passed to a following vessel, whilst a substantially clear solution is continuously passed to a preceding vessel.—B. N.

Sintering fine ores, flue-dust, purple ore and the like; Process for——. C. Giesecke, Bad Harzburg, Germany. U.S. Pat. 1,205,944, Nov. 21, 1916. Date of appl., Aug. 30, 1916.

FINELY-DIVIDED material containing iron is sintered by first mixing and agglomerating the material with a finely-divided fuel, and with slimes containing a high proportion of clay, and the agglomerated material is subjected to pressure to form it into more or less regular bodies. Fuel is distributed in the form of small lumps over the bodies, and in the interstices between them, in a sintering furnace, and the material is rapidly heated and cooled.—B. N.

Ingot; Method of making——. J. E. York, New York. U.S. Pat. 1,206,188, Nov. 28, 1916. Date of appl., Mar. 21, 1913.

METAL in "piece form" is inserted into the zone of the ingot, where "pipes" and segregations occur, whilst the metal in the interior is mobile, and the metal is gradually displaced to fill the "pipes," at the same time expelling the portion containing the segregations to the exterior. Metal is fed in to compensate for the portion flowing into the cavities, and the extruded metal is heated at the issuing point to maintain its mobility.—B. N.

Pickling process (for copper). E. F. Hitch, Assignor to Western Cartridge Co., East Alton, Ill. U.S. Pat. 1,206,220, Nov. 28, 1916. Date of appl., Aug. 25, 1916.

COPPER and metals containing copper are cleansed by pickling in a bath containing sodium bisulphate and an oxidising agent, such as sodium bichromate.—B. N.

Vanadium ores; Lixiviation of——with alkali sulphide solution. G. Fester, Breslau. Ger. Pat. 394,932, June 23, 1914.

THE ore is treated, in a counter-current apparatus,

with an aqueous solution of alkali sulphide, polysulphide, or hydrosulphide, with or without the application of heat and/or pressure. The resulting alkali vanadate solution is purified by treatment with chlorine or other similar oxidising agent, and then treated in the usual way.—A. S.

Rabbling appliances for mechanical ore roasting furnaces. J. Harris, Sheffield. Eng. Pat. 102,591. Aug. 17, 1916. (Appl. No. 11,650 of 1916.)

Metallic deposits; Process of producing——. F. A. Roux, Assignor to Soc. L'Aluminium Français, Paris. U.S. Pat. 1,207,218, Dec. 5, 1916. Date of appl., Jan. 19, 1911.

SEE Fr. Pat. 464,721 of 1913; this J., 1914, 599.

Silvering or gilding metal articles; Preparation for——. A. Dalby, London. U.S. Pat. 1,208,597, Dec. 12, 1916. Date of appl., July 22, 1916.

XI.—ELECTRO-CHEMISTRY.

Batteries; Pocket lamp——. K. Arndt, Chem.-Zeit., 1916, 40, 1017—1019.

THE dry batteries for pocket electric lamps are made almost exclusively on the principle of the Leclanché cell. A battery of three cells joined in series, gives initially a voltage of about 4.5, and will yield 3 watt-hours of energy at a continuous discharge rate of 0.2 amp. The capacity of individual batteries varies according to the purity of the materials used. Impurities tend to cause local chemical action and short circuiting. The following measurements were made on different

varieties of carbon powder after compressing at (25 atm. (1875 lb. per sq. inch).

Nature of carbon	Ash content.	Density.	Specific conductivity (in reciprocal ohms).
Acheson (electric furnace) ..	(0.2 2.1 5.7 7.7 20.0	1.61 1.47 1.59 1.73 1.79	93 85 53 93 52
Natural graphite			
Acetylene black	0.0	0.61	4

On mixing with manganese dioxide, the conductivity is greatly lowered. A determination of the amount of zinc and manganese dioxide entering into chemical reaction during the production of a measured amount of current, showed that the amount of chemical change is about twice that calculated from the current. The difference represents the loss through local chemical action. In the practically exhausted cell, about two-thirds of the manganese dioxide and of the zinc remains unaffected. It is estimated that, in Germany, 30 millions of these batteries are manufactured annually, representing a consumption of 300 tons of the constituent materials.—J. N. P.

PATENTS.

Electric arc furnace. C. W. H. von Eckermann, Ljnsne, and I. Rennerfelt, Djursholm, Sweden. U.S. Pat. 1,206,057, Nov. 28, 1916. Date of appl., July 15, 1915.

AN electric arc furnace with a horizontally elongated crucible, is provided with several systems of electrodes, each system being located in a plane perpendicular to the longitudinal axis of the furnace; means are provided for connecting the electrodes to a three-phase alternating current so as alternately to produce arcs between the electrodes of each system, by connecting each system in one phase of the circuit, and between the electrodes and the charge in the furnace by connecting the electrodes in Y-connection with the charge as neutral point.—T. H. B.

Furnace control apparatus; Electric—. J. A. Seede, Schenectady, N.Y., Assignor to General Electric Co. U.S. Pat. 1,206,663, Nov. 28, 1916. Date of appl., Apr. 12, 1916.

IN an apparatus for regulating furnace electrodes, the electrode is mechanically connected to, and moved by, a reversible electric motor, an electromagnetic device, responsive to variation of energy in the electrode supply circuit, being provided for controlling and reversing the motor. A dynamic braking means is interlocked with the relay magnet to close the armature circuit of the motor through a resistance, in order to brake the motor when the supply circuit is open, and an electromagnet cut-out is provided for de-energising the motor when the voltage of the current in the electrode circuit falls below a predetermined value.—B. N.

Accumulators; Electric—. M. and A. Fetscher, Mergentheim. Ger. Pat. 294,860, Jan. 14, 1914.

THE electrodes consist of a mixture of lower

manganese oxides and of manganese dioxide, respectively, whilst the electrolyte is a slightly alkaline solution of potassium nitrate. The manganese oxides may be used in the form of compressed blocks or in combination with metallic fillers. In these accumulators the metallic portions are not attacked by the electrolyte and the formation of active oxygen is prevented.—W. P. S.

Ultra-violet rays; Method of obtaining—by spark discharge. J. von Kowalski-Wierusz, Fribourg, Switzerland. U.S. Pat. 1,207,347, Dec. 5, 1916. Date of appl., Apr. 10, 1914.

XII.—FATS; OILS; WAXES.

Arachis oil; Detection of—in admixture with olive oil. R. Biazzo and S. Vigdoreik. Annali Chim. Appl., 1916, 6, 179—185.

A SOLUTION of the fatty acids from 20 grms. of the oil under examination in 200 c.c. of ether is shaken vigorously for 5 mins. with 50 c.c. of a 30% aqueous solution of normal lead acetate. The lead soaps of the liquid fatty acids dissolve in the ether, whilst the insoluble lead soaps of the solid acids form an intermediate layer between the aqueous solution and the ether. If a persistent emulsion forms in the aqueous layer, the latter is filtered through a wet filter and the particles of insoluble soap on the filter returned to the separating funnel. The clear ethereal solution is decanted through a dry filter, the residual insoluble lead soap washed with 75 c.c. of ether, then transferred to the filter and again washed with ether. The residue on the filter is transferred to a separating funnel with 200 c.c. of ether, treated with two successive quantities of 100 c.c. of 20% hydrochloric acid, the ethereal solution of the liberated fatty acids washed with water, dried, filtered, evaporated, and the residue tested for arachidic acid by one of the known methods. For the detection of arachidic acid the authors use the method of Kreis and Roth (this J., 1913, 201) slightly modified, and for its determination the method of Tortelli and Ruggeri (this J., 1898, 876).—A. S.

Rape oil; Detection of—in admixture with olive oil. R. Biazzo and S. Vigdoreik. Annali Chim. Appl., 1916, 6, 185—195.

THE method proposed depends upon the concentration of erucic acid by means of the process of Fachini and Dorta (this J., 1912, 397), its conversion into behenic acid by hydrogenation, and identification of the behenic acid. The fatty acids from 20 c.c. of the oil under examination are dissolved in 180 c.c. of anhydrous acetone, and the solution is heated nearly to boiling and treated with 20 c.c. of N/1 potassium hydroxide solution. After cooling, the precipitated acid potassium soaps are filtered off, washed four times with cold acetone (10 c.c. each time), then dissolved in water, decomposed with hydrochloric acid, and the fatty acid, dissolved in ether. The

etheral solution is shaken with lead acetate solution and the insoluble lead soaps treated for the detection of arachidic acid (see preceding abstract). The lead soaps remaining dissolved in the ether are decomposed with hydrochloric acid, and the liberated fatty acids in etheral solution are hydrogenated in presence of palladium prepared by Loew's method (this J., 1890, 550). The hydrogenated fatty acids are subjected to fractional crystallisation as in the method of Kreis and Roth (this J., 1913, 201) for the detection of arachidic acid: if the least fusible fraction has a melting point higher than 71° C. the presence of rape oil is indicated.—A. S.

"*Solvines*" (Turkey-red oils); *Biological valuation of the so-called* —. R. Kobert and W. Grönel. Collegium, 1916, 261—266, 305—311. Z. angew. Chem., 1916, 29, Ref., 505.

EXPERIMENTS have shown that indications of the strength and action of commercial Turkey-red oils can be obtained from experiments with blood corpuscles. When exposed to the action of Turkey-red oil, blood corpuscles dissolve to a red liquid, and then after a very short time the blood colouring matter is decomposed into glutin and hæmatin, and a turbidity is produced. The constituents of Turkey-red oil producing the effects described are the same as those to which its value in the dyeing and tanning industries is due. The sodium salts of polycinnoleic acids resemble saponins in many respects, and it is not improbable that saponins could be used as substitutes for Turkey-red oil in the tanning industry.—A. S.

Water content of margarine prepared from hydrogenised fats. Brauer. See XIXA.

PATENTS.

Titanic oxide products [pigments]; Method for producing composite —. L. E. Barton, Niagara Falls. Assignor to The Titanium Alloy Manufacturing Co., New York. U.S. Pat. 1,205,144, Nov. 21, 1916. Date of appl., Apr. 23, 1915.

A SOLUTION of titanic sulphate is treated with a base, such as calcium hydroxide, giving an insoluble sulphate, and the mixture heated to produce a mixed precipitate of this sulphate with basic titanic sulphate. Sulphuric acid may be added to the titanic sulphate solution before adding the base.—B. V. S.

Paints. A. J. Rossi, Niagara Falls, and C. M. E. Schroeder, Rutherford, N.Y., Assignors to The Titanium Alloy Manufacturing Co., New York. U.S. Pats. (A) 1,205,267, (B) 1,205,268, and (C) 1,205,269, Nov. 21, 1916. Dates of appl., (A) Nov. 19, 1912, (B) and (C) May 7, 1915.

(A) AMORPHOUS white titanic oxide (TiO_2) is incorporated, without chemical combination, with other substances to form a white paint. It may also be mixed, in a proportion of not less than 96%, with iron oxide to form a yellowish or buff paint. (B) An addition of white lead may be made to paints prepared as in (A). (C) Zinc oxide may form a constituent of the paints claimed in (A). —C. A. M.

Composition; Binding and coating —. C. Ellis, Montclair, N.J., Assignor to Ellis-Foster Co. U.S. Pat. 1,189,519, July 4, 1916. Date of appl., Mar. 29, 1910.

A SLOW-DRYING "pitchy" paint for iron and

steel-work is made up of guayule resin, 80; benzol, 40; Japan drier, 20; and red iron oxide (or other pigment), 100 parts. Another paint-composition is made by boiling guayule resin with 0.5 to 1.0% of litharge, manganese borate, or similar drier, and thinning with turpentine, benzol, etc. Guayule resin is advantageously used where ordinary paint is affected by the liquids with which it comes in contact. Another paint consists of guayule resin, 75; linseed oil or other drying oil, 10; Japan drier, 20; turpentine, 45; and red iron oxide, 100 parts. An elastic paint consists of linseed oil, 4; guayule resin, 4; copal resin, 1; and turpentine, 3 parts, coloured with white or sublimed lead, zinc oxide, lithopone, etc. A paint for cement is made up of Pontianak resin, 3; guayule resin, 1; benzine, 4; and benzol, 2 parts, together with pigment, and Portland cement as a thickener. Guayule resin may be stiffened by heating it with 3 to 5% of hydrated lime or zinc oxide, for the production of hard surfaces. A shingle stain is prepared from guayule resin, 20; copper oleate (or copper oxide dissolved in guayule resin at 140° C.), 1; benzol, 15; and Japan drier, 5 parts, and pigment. For reinforced concrete protection, a paint may be prepared by adding guayule resin, 50, to melted Pontianak resin or ordinary resin, 25, then thinning with benzol, 50, and adding Portland cement 50 parts. A steel protective dubbing is obtained by dissolving chromium sesquioxide, 1, in guayule resin, 10 parts, and thinning with benzol; or the resin may be treated with 5—8% of its weight of caustic soda in aqueous solution and precipitated with chrome alum. A priming for cement work is made by mixing guayule resin, 10; Pontianak resin, 20; fatty acids from linseed oil, 5; and benzol, 15 parts.—E. W. L.

Coating composition [for concrete]. C. Ellis, Montclair, N.J., Assignor to Ellis-Foster Co. U.S. Pat. 1,189,550, July 4, 1916. Date of appl., July 25, 1911.

THE composition consists essentially of a substantial proportion (20—35%) of unsaponifiable, resinous, finish-forming material, such as Pontianak or Jelutong resin, together with a thinner, such as coal-tar naphtha, and a colloidal "bodying" agent such as vulcanised oil (e.g., vulcanised tung oil). For example (1) Pontianak resin, 1 part, is melted and thinned with light coal-tar naphtha, 2 parts; (2) Pontianak resin, 4; ceresin or montan wax, 1; and naphtha, 8 parts; (3) Pontianak resin, 8; spindle oil, 1; tung oil, 1; and naphtha, about 16 parts. (1) For a glossy finish, Pontianak resin, 8; kauri resin, 2; boiled tung oil, 1; fish oil, 1; and naphtha, 6 parts. The Pontianak resin may be either raw or heat-treated (e.g., for one hour at about 320° C., 15 hrs. at about 200° C., or 12 hrs. at about 230° C.). In the former case the coal-tar naphtha may be replaced by petroleum naphtha to the extent of 10—20%. As thickeners, polymerised tung and other oils, aluminium tungate, the aluminium soap of fish oil, rubber, and certain waxes are serviceable. The following formula is illustrative of a thickened composition for general purposes:—Jelutong resin, heat-treated, 25; ceresin, 2; oil-soluble compound from cotton-seed oil and sulphur chloride, 8; tung acids, 10; Japan drier, 1; benzol, 30; and petroleum benzine, 24 parts. Pigments fast to cement alkali may be used to colour the composition.—E. W. L.

Preparation [artificial resin] for treating teeth. J. A. Albrecht, Frankfurt, Germany. U.S. Pat. 1,205,957, Nov. 28, 1916. Date of appl., Jan. 4, 1913.

A SOLUTION of a phenol (resorcinol) in formaldehyde is diluted with a viscous retarding agent (glycerin), and mixed with a condensing agent, to

obtain a preparation which will readily penetrate into the smallest cavities in the teeth, and slowly harden there, at the temperature of the body, without liberating any objectionable amount of heat.—C. A. M.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Ceara rubber from Nigeria. Bull. Imp. Inst., 1916, 14, 382—384.

Two samples of Ceara rubber, prepared from latex tapped by the Lewa system from trees growing in the Government plantation at Ankpa, Bassa, Northern Provinces, Nigeria, consisted of rough sheets, and were valued at 2s. to 2s. 1d. per lb. and 2s. 4d. to 2s. 6d. per lb. respectively in London (with plantation Para crêpe at 2s. 1d.—2s. 4d. and 3s. 4d. per lb. respectively). The physical properties of the samples were satisfactory and the analytical results were: loss on washing 5.3, and 8.0%; on original sample; and caoutchouc, 83.1, 84.7; resins, 5.3, 6.3; protein, 9.9, 7.7; and ash, 1.7, 1.3%, on the dry washed rubber. A comparison of the second sample with plantation Para sheet, with regard to their behaviour on vulcanisation gave the following results: time of cure at 50 lb. steam pressure, Ceara 50 min., Para sheet 70 min.; tensile strength, 2330, 2300—2400 lb. per sq. in.; elongation 847, 875%. The ages of the trees from which the two samples were obtained were, respectively, 3 years and 3—4 years, their average girth being 15 in. and 18—20 in. at 3 ft. from the ground.

—E. W. L.

Vulcanisation tests. L. E. Campbell. Bull. Dep. Agric., Ceylon, 1916, No. 24. India Rubber J., 1916, 52, 831—832. (Cf. this J., 1916, 1226.)

AN investigation has been carried out at the Imperial Institute, on the effect of the form of raw plantation rubber, the method of drying, and the effect of "overworking" the freshly-coagulated rubber, upon time of vulcanisation, tensile strength, elongation, and permanent set. The results show that the conversion of the freshly-coagulated rubber into crêpe, lengthens the time of vulcanisation, but that, a further, even excessive, "working" of the rubber has little effect. The effect upon tensile strength and elongation is very small. Permanent set was satisfactorily low (1.00—3.44%) in each case. The method of drying—in air at ordinary temperature, in hot air, in a vacuum dryer—has very little effect upon tensile strength or time of vulcanisation. The average tensile strength of all samples examined was fully equal to that of specimens of best hard Para; the average elongation at break was only very slightly lower.—E. W. L.

Vulcanised rubber; Relationship of mechanical to chemical properties of. D. Spence. India Rubber J., 1916, 52, 861. (Cf. this J., 1916, 550.)

EXPERIMENTS made during the past few years

indicate that the combined sulphur at "optimum cure" in the case of *Hevea* plantation rubber is a remarkably constant quantity, equal on the average to approximately 2.8—3.0%. Where more than this amount of combined sulphur has been found, either the method of vulcanisation is at fault, or the means of determining the "optimum cure" is inaccurate. Where the time of cure is prolonged, higher combined sulphur at the "optimum" point will probably be found: depolymerisation, requiring an increase in cure to bring the rubber up to the apparent physical optimum, leads to an increase in combined sulphur over the amount given above. The rubber is nevertheless over-cured. The constancy of the value for combined sulphur leads the author to regard the relation between rubber and sulphur as stoichiometric. It has been observed that the physical properties of pure balata undergo, on vulcanisation, a sudden change in the direction of those of rubber, at a combined sulphur content of about 3%.—E. W. L.

PATENT.

Rubber composition and art of manufacture: Dental.—S. G. Supplee, E. Orange, N.J., and C. J. R. Engstrom, Los Angeles, Cal. U.S. Pat. 1,201,609, Nov. 14, 1916. Date of appl., Feb. 19, 1916.

A PLASTIC composition consisting of a mixture of finely-divided vulcanised, and unvulcanised rubber, is vulcanised, when, it is claimed, the expansion of the one ingredient is off-set or counteracted by the shrinkage of the other.—E. W. L.

XV.—LEATHER; BONE; HORN; GLUE.

Tanning; Theory of vegetable.—H. R. Procter and J. A. Wilson. Chem. Soc. Trans., 1916, 109, 1327—1334.

TANNINS give colloidal sols with water, each tannin particle having a negative charge. The surface layer of solution immediately surrounding the particles has therefore a certain concentration of positive ions bound electrochemically to the tannin; this concentration is called $[M^+]$. If some of the electrolyte MN be added to the solution, there will be now some unbound M^+ in the surface layer, so that in this layer $[M^+]$ and $[N^-]$ will be unequal, though necessarily equal in the bulk of the solution. This is a case to which Donnan's results on membrane equilibria are applicable, and it can consequently be shown that

$$[M^+]_s \times [N^-]_s = [M^+]_b \times [N^-]_b,$$

s and b denoting the concentrations in the surface layer and in the bulk of the solution respectively. The equation refers to diffusible ions. Let x represent the concentration of positive or negative ions in the bulk of the solution, y the concentration of negative diffusible ions, and z that of bound ions in the surface layer, then $y+z$ is the concentration of positive ions, and

$$x^2 = y(y+z).$$

The difference in distribution of ions in the bulk of the solution and in the surface layer gives rise to a potential difference according to the equation

$$E = \frac{RT}{F} \log \frac{1}{\lambda}, \text{ where } \lambda = \frac{y}{x}, \text{ and therefore}$$

$$E = \frac{RT}{F} \log \frac{2x}{-z + \sqrt{4x^2 + z^2}} = 0 \text{ when } x = \infty.$$

Thus E diminishes with increasing concentration of electrolytes in the solution, and when sufficiently small, establishes a condition favourable to the coalescence of tannin particles and their precipitation. Similarly between a colloid

jelly such as hide, and an acid solution, in which it is immersed, a potential difference will exist, which is opposite in sign to that existing in the case of tannin. Thus when hide is immersed in a slightly acid tannin solution, electrical neutralisation and co-precipitation of the two colloids follows their mutual approach. This is the fundamental action in vegetable tanning. Tannins for which z is higher than for others will give the greatest potential difference between surface layer and bulk of solution, will combine most rapidly with hide, and will give the most stable leather. A table giving the values of z for various tannins under uniform conditions would be of great value. The rate of tanning for a given tannin concentration is a maximum when the potential differences are of opposite sign and the absolute value of each is a maximum. With increasing concentration of electrolyte, the potential differences diminish, until the tannin must precipitate alone, and the collagen shrink to a hard mass. In alkaline solution, when both colloids have negative charges, there is no combination. The above reasoning is applicable to many other colloid problems, such as those involved in dyeing.—F. C. T.

Alkali sulphides [in tannery lime liquors]; Determination of—D. McCandlish and J. A. Wilson. J. Amer. Leather Chem. Assoc., 1916, 11, 598—602. (See also Bennett, this J., 1916, 1124.)

The presence of ammonia in standard zinc sulphate solutions is useful for the titration of solutions of sodium sulphide alone, but not when lime is also present, even though the precipitation of zinc hydroxide is prevented. Zinc hydroxide is less soluble than zinc sulphide, and the titration would be impossible but for the more complete ionisation of the hydroxide. When the titration is nearing the end point, the solution is saturated with zinc sulphide, and the following relations hold:

(1) $[Zn^{++}] \times [S^{--}] = K_1$ (solubility-product constant)

(2) $[Zn^{++}] \times [OH']^2 = K_2[Zn(OH)_2]$

and therefore (3) $[S^{--}] = \frac{K_1[OH']^2}{K_2[Zn(OH)_2]}$

and with a solution saturated with zinc hydroxide, $[Zn(OH)_2]$ is fixed, and (3) may be expressed in the form:

(4) $[S^{--}] = K_3[OH']^2$

which gives the minimum value for $[S^{--}]$, which is necessary for the end point, the denominator in (3) being at a maximum. Any further addition of zinc ions will cause a precipitation of both zinc sulphide and hydroxide in such proportion as to satisfy (4). Any increase in $[OH']$ increases $[S^{--}]$ and also the error of titration, as is readily shown by the addition of sodium hydroxide. Ammonium chloride diminishes $[OH']$. Experiments showed that 25—40 c.c. of concentrated ammonia per litre in $N/10$ zinc sulphate solutions, with or without ammonium chloride, caused a slight increase in small titrations, owing to the retention of zinc as zinc ammonium ions. This increase becomes indefinitely large by the addition of more and more ammonia. The zinc solution without ammonia is thus not unworkable as Bennett states, though on the other hand no form of zinc solution gives correct results in all cases, strong solutions causing especial difficulty. With regard to Bennett's criticism of the authors' copper method, it is maintained that the equation

$4CuSO_4 + 4H_2S = 2CuS + Cu_2S + S + 4H_2SO_4$ sometimes held to represent the action of hydrogen sulphide on copper sulphate, shows an exact relation between copper and sulphur. Further Schirpf maintains that the action of sodium sulphide on an acid solution of copper sulphate

(as in the authors' method) invariably gives cupric sulphide. It should be remembered that the unprecipitated copper is estimated.—F. C. T.

Biological valuation of the so-called "solvinces" (Turkey-red oils). Robert and Greuel. See XII.

PATENTS.

Tanning substances; Manufacture of—H. Wade, London. From Deutsch-Koloniale Gerbu-Farbstoff Ges. m.b.H., Karlsruhe, Germany. Eng. Pat. 18,174, Dec. 30, 1915.

TANNING substances are obtained by the action of formaldehyde or a substance capable of yielding formaldehyde on aminonaphtholsulphonic acids or dihydroxynaphthalenesulphonic acids, as such or in the form of their salts, in aqueous or slightly acid solution.—F.W. A.

Leather; Composition for finishing and dressing—T. Sandlant, Masterton, New Zealand. Eng. Pat. 17,702, Dec. 7, 1915.

A COMPOSITION for finishing and dressing leather for furniture, etc., consists of three parts each of hard drying elastic varnish, methylated spirit, and petroleum, one part of boiled linseed oil, and six parts of benzine and/or benzol. Pigments may be added as desired. The composition may also be used for the renovation of old and worn leather.—F. C. T.

XVI.—SOILS; FERTILISERS.

Committee on supplies of fertilisers.

THE Food Controller has appointed a Committee to make such arrangements as may be necessary and expedient for the increase of supplies of fertilisers in the United Kingdom, and for controlling so far as may be necessary their output and distribution. The following are the members of the Committee:—Capt. Charles Bathurst, M.P. (chairman); Mr. H. R. Campbell; Sir James J. Dolbie, F.R.S.; Mr. R. R. Enfield; Capt. R. B. Greig; Mr. T. H. Middleton, C.B.; Mr. W. Anker Simmons; Professor W. Somerville; Mr. G. J. Stanley, C.B., C.M.G.; Mr. R. J. Thompson; and Professor T. B. Wood. Mr. H. Chambers will be the secretary to the Committee.

Evaporation of moisture from the soil; Factors affecting the—F. S. Harris and J. S. Robinson. J. Agric. Res., 1916, 7, 439—461.

To ascertain the effect on evaporation of the initial amount of water present in a soil, small or large shallow vessels made of metal or glass were charged with loam, sand, clay, or muck (vegetable mould) soil, with definite water contents, and allowed to dry for periods varying from 13 to 51 days. Weighings were mostly taken daily, and after each weighing water was added to restore the original moisture content. It was found that evaporation increased with the initial water content of the soil, that the increase was relatively less when the original water content was high, and that in most cases more evaporation took place from soils containing more than 20% of moisture than from pure water itself. The evaporation curves showed the presence of various critical points where the

rates of loss changed rapidly. Evaporation diminished greatly when the humidity of the air was increased and when the intensity of sunshine was reduced. The influence of wind velocity was determined by driving air-currents, produced by electric fans, over soils contained in copper vessels of 6 in. diameter, placed in alleys 70 in. long by 8½ in. wide, one alley receiving no air current. Evaporation increased *pari passu* with increased wind velocity up to 10 miles per hour, but above that velocity the increased evaporation was very slight. Experiments made with quartz sand of five different grades of fineness and placed in copper vessels 1–3 cm. above a free water surface, showed that evaporation was somewhat greater for the finer particles. The effect of mulches of varying depths was ascertained by placing quartz sand or river sand on wire-gauze covered with cheesecloth about 1 cm. above the surface of some water in the same vessel, thereby eliminating capillary action. A ½-inch mulch reduced the evaporation by about 63%, a 1-inch layer by about 66%. Dry mulches composed of fine particles are apparently less effective than others containing coarse particles. Slight changes in temperature exerted a marked effect upon evaporation; compacting the surface soil also increased it but only to a depth of 4 inches. Evaporation was reduced by adding dissolved salts in high concentration.

—E. H. T.

Nitrification in semi-arid soils. W. P. Kelley, J. Agric. Sci., 1916, 7, 117–137. (See also this J., 1915, 808; 1916, 61.)

LABORATORY tests on a light sandy loam soil containing 1% of dried blood showed that nitrification proceeded actively in the virgin soil, manured, and control plots, but that little or no nitrification took place except in the presence of manure. On the other hand, the nitrogen of dried blood was actively nitrified under field conditions where relatively very much less fertiliser was added. Subsequent laboratory experiments proved that when dried blood was added to the soils in amount approximating to that used in the open, the nitrogen was readily converted into the nitric state. Comparative tests with bone meal, ammonium sulphate, and dried blood, on soil from the same plots, showed that the concentration of the fertilisers had a very marked effect upon nitrification. Thus 1% of dried blood in certain soils remained unnitritified when 1% of bone meal and 0.2–0.3% of ammonium sulphate were actively nitrified; but 0.06% of dried blood was readily converted. This inability to nitrify 1% of dried blood was found to apply to widely different soil types of southern California. When bone meal and ammonium sulphate were applied in amounts containing the same quantity of nitrogen as 1% of dried blood, they too remained largely unnitritified. The period of incubation was also shown to have a marked effect upon the rate of nitrification, in fact directly contradictory results could be obtained by varying the period of incubation; in the above tests a period of 4 weeks was selected. The nitric nitrogen was determined by the phenolsulphonic acid or by the aluminium reduction method, but the former is untrustworthy when large amounts are present, and the latter method fails in presence of much nitrite. The conclusion is drawn that much of the laboratory work hitherto done on rates of nitrification is invalidated by the neglect of the two factors—concentration of fertiliser and period of incubation. Investigation of the nitrification in a dark-coloured clay loam soil showed that, given adequate aeration, this process could take place down to 5 ft. below the surface, and the results also emphasised the importance of using the fertilisers in low concentrations. The influence of added

sodium carbonate or sulphate varied greatly with the concentration of the nitrogenous fertiliser employed. Thus 0.05% of the carbonate inhibited the nitrification of 1% dried blood, but 0.04% did not affect the conversion of 0.1% of the fertiliser. Similarly, 0.1% of sodium carbonate was toxic to the nitrification of 0.15% of ammonium sulphate, but stimulated the oxidation when 0.0625% only of ammonium sulphate was present. Under artificial and abnormal conditions, e.g., excess of nitrogenous fertiliser, presence of considerable amounts of alkali salts, nitrite accumulates in field soils, and in certain cases oxidation may not proceed beyond the stage of nitrite, although nitrifying organisms may be present in abundance. Nitric nitrogen is best determined in presence of nitrite by the phenol-sulphonic acid method, after the nitrite has been decomposed by evaporating the soil-extract with 10 c.c. of a 1% ammonium sulphate solution.

—E. H. T.

Phosphoric acid: Conversion of soluble — into insoluble phosphoric acid in the soil under the influence of physical, chemical, and biological factors. S. Skalkij, Agric. Gaz. of Southern Russia, 1915, 17, Bull. Agric. Intell., 1916, 8, 1081–1086.

THE fixation of water-soluble phosphoric acid depends on the chemical, physical, and biological factors of the soil; the intensity of total fixation of the acid is in direct relation to the cultural conditions of the soil and increases with the addition of potassium nitrate. The fixation proceeds with greater intensity in natural soil than in soil in which bacterial life has been destroyed by addition of chloroform. The total intensity of fixation and the physical and chemical fixation of water-soluble phosphoric acid are less in the arable layer (from 0 to 17.7 cm. depth) than in the layer lying immediately beneath (from 17.7 to 35.5 cm.), whilst the intensity of the assimilation of phosphorus is greater in the arable layer than in that immediately beneath. The number of bacteria increases with improvement of the cultural condition of the soil and there is, possibly, a relation between the quality of the bacterial flora and the intensity of assimilation of phosphorus.—W. P. S.

Sodium salts: Effect of — on the absorption of plant food by wheat seedlings in water cultures. J. F. Breazeale, J. Agric. Res., 1916, 7, 407–416.

HARD wheat (*Triticum vulgare*) was grown in a nutrient solution containing, in parts per million: 200 NO_3 as sodium nitrate, 200 K_2O as potassium chloride, 130 P_2O_5 as sodium phosphate, and an excess of calcium carbonate. About 1000 seeds were germinated in 2500 c.c. portions of this solution, and after 2 days the chloride, sulphate, or carbonate of sodium, was added in concentrations varying from 50 to 1000 parts per million. After 21 days' growth the green and dry weights, the nitrogen, phosphoric acid, and the potash contents of 100 representative plants from each culture were determined. When present in concentrations up to 1000 p.p.m., none of the sodium salts affected the absorption of nitrogen by the plants. Sodium chloride up to 1000 p.p.m. had no effect on the P_2O_5 -intake, but decreased slightly that of the potash. The sulphate (1000 p.p.m.) caused the absorption of potash and phosphoric acid to fall to about 70% that of the controls, when expressed as percentage of dry weight of the plants. The depressing effect of sodium carbonate was apparent when only 100 p.p.m. were present; with 1000 p.p.m. the potash absorption fell to 20%, and the phosphoric acid absorption to 30% that of the control. The

inhibiting action of the chloride and sulphate may have been due to their interaction with calcium carbonate to form sodium carbonate.—E. H. T.

Sodium nitrate and ammonium sulphate; Comparison between the effects of manuring potatoes with —. A. Zasukhin. *The Farm (Russia)*, 1916, 11, 297—304. *Bull. Agric. Intell.*, 1916, 8, 1114—1116.

PLOTS manured with ammonium sulphate (264 lb. per acre) yielded larger crops than did similar plots treated with sodium nitrate (396 lb. per acre), and larger crops were obtained by applying the ammonium sulphate directly to the tubers during planting than by spreading it before planting. When the sodium nitrate was applied to the tubers, the development of the potato in its first period of growth was considerably retarded, but as regards the crop, the effect appeared to be equal whether the nitrate was applied to the tuber or spread before planting. By giving half of the nitrogen in the form of sodium nitrate to the tuber, and the other half in the form of ammonium sulphate to the soil, no advantage was secured as compared with manuring the potato with ammonium sulphate alone.—W. P. S.

Dicyanodiamide; Determination of — in nitrolim [crude calcium cyanamide]. A. Stulzer. *Z. angew. Chem.*, 1916, 29, 417—418.

THE error attendant on the determination of dicyanodiamide in crude calcium cyanamide (see Hager and Kern, this J., 1916, 974) may be minimised by extracting with ten times the weight of 94% alcohol, instead of with water, whereby only small quantities of unchanged cyanamide, either free or as the calcium salt, pass into solution along with the dicyanodiamide present, and only traces of the latter are then carried down with the subsequent small precipitate of silver cyanamide. The error due to decomposition of dicyanodiamide by the sodium hydroxide added to reprecipitate its silver salt from the ammoniacal solution is more difficult to obviate, but by keeping the concentration of the alkali within prescribed limits, it does not exceed 5% of the total dicyanodiamide present. It is immaterial whether the ammoniacal liquid is evaporated after addition of sodium hydroxide or not. The modified procedure is as follows:—10 grms. of nitrolim is extracted for 2 hours with 100 c.c. of 94% alcohol, and after filtration, the total soluble nitrogen is determined in 20 c.c.; and to another 50 c.c., 180 c.c. of water is added, followed by 10 c.c. each of 10% silver nitrate and 10% ammonia. The precipitate represents the alcohol-soluble cyanamide in 5 grms. of sample, and 200 c.c. of the undiluted filtrate, representing 4 grms. of sample, is treated with 50 c.c. of 10% sodium hydroxide, and without heating, the precipitate of silver dicyanodiamide filtered off, washed, and determined in the usual way.

—G. F. M.

Fertilisers; Effect of large applications of — on carnations. G. D. Beal and F. W. Muncie. *J. Amer. Chem. Soc.*, 1916, 38, 2784—2804.

THE effect upon carnations of large applications of dried blood, sodium nitrate, ammonium sulphate, acid calcium phosphate, disodium phosphate, and potassium sulphate, and in some cases also sodium chloride and sodium sulphate, to the soil in which they were grown has been determined, the injurious effect characteristic of excess of each fertiliser being recorded. The rapidity with which the plants became affected was, in general, in the order of the solubilities of the fertilisers employed. Determinations of dry weight and of ash made on the foliage of the plants showed an increase in

both values with increased applications of the fertilisers, whilst analysis of the mineral constituents of the foliage showed an increased content of the fertilising salt after large applications. Osmotic pressure determinations made on the sap showed that the degree of injury varied with the osmotic pressure, the increase of osmotic pressure being accompanied by an increase in the total solids and ash of the sap and in the amount of the fertiliser taken up by the plant, but the injury is not a result of increased osmotic pressure exclusively.—T. C.

Boron; Influence of — on plant growth. J. A. Voelcker. *J. Roy. Agric. Soc.*, 1915, 76, 317—351. *Bull. Agric. Intell.*, 1916, 8, 1100.

POT experiments were made as to the effect of boric acid and borax on wheat and barley; the quantities of boron compounds added were equivalent to 0.0001—0.10% of the element, calculated on the whole content of each pot. Germination was retarded by the presence of more than 0.003% of boron and even 0.001% of boron, especially when added in the form of borax, appeared to have some effect. Quantities of more than 0.001% of boron, whether added as boric acid or borax, prevented the plants from developing and forming grain. A toxic influence was noticed with 0.0005% of boron, but quantities not exceeding 0.00025% had a slight stimulating action. The effects generally were more marked in the case of borax than with boric acid. (See also Cook, this J., 1916, 319.)

—W. P. S.

Humic substances in decomposing leaves; Amount of —. A. C. Trusov. *Agric. and Sylvicult.*, Petrograd, 1916, 76, 339—361. *Bull. Agric. Intell.*, 1916, 8, 1096—1098.

THE quantity of soluble humic substances in decomposing leaves varies according to the stage of decomposition; for instance, maple leaves after 4 days' decomposition contain 1.93% of water-soluble humic substances and this is about 50% of the total humic substance present. During the decomposition, the quantity of water-soluble humic substances at first increases and then decreases; this shows that humic substances are formed during the first brief period of decomposition of vegetable detritus and that the humic substance itself subsequently undergoes decomposition. The ratio between the quantity of water-soluble humic substance and that soluble in ammonia varies with different leaves and with the degree of decomposition. When leaves are subjected to repeated desiccation, the quantity of humic substance decreases. The quantity of humic substances formed does not increase after 8 days, and after 156 days its solubility in water disappears completely. (See also this J., 1915, 808; 1916, 132, 616.)—W. P. S.

Peat; Treatment of — for manurial and other purposes. W. B. Bottomley, London, Eng. Pat. 16,658, Nov. 25, 1915. (See this J., 1913, 878.)

IN the aerobic treatment of peat previously described, the resulting fertiliser owes its efficacy to the presence of auxinones, and not directly to that of ammonium humates. The initial neutralisation of the peat is much accelerated by sprinkling it in a 6-inch layer with sodium carbonate, in amount equal to about 3% of the weight of

anhydrous peat, dissolved in about five times its weight of water. Further acceleration is effected by then breaking down the cellular tissue with live steam at about 60 lb. pressure in a tank containing perforated steam pipes and covered loosely. This action takes about 30 mins. per ton of peat. After the material has been spread on a heated floor in a 1 ft. layer, water containing ammonifying and nitrifying organisms is sprinkled over it, and then the product is maintained at 26°—28° C. for about three days.—E. H. T.

Fertilisers. G. Defries, London, Eng. Pat. 17,381, Dec. 11, 1915.

NATURAL guano is successively treated with sulphur dioxide and ammonia, or is treated with a solution of ammonium sulphite, and the ammonium sulphite oxidised to sulphate by exposure to air.—B. V. S.

Fertiliser [from molasses]; Process of producing a stable——. L. Wilkening, Hanover, Germany. U.S. Pat. 1,205,829, Nov. 21, 1916. Date of appl., Jan. 14, 1915.

A DRY, stable, non-hygroscopic fertiliser is obtained by the fermentation of a mixture of residues of molasses and an absorbent fibrous material such as peat. The fermentation may be produced by the addition of decomposed stable

acetate. The author recommends treatment with lead acetate and alcohol, as proposed by Chauvin (this J., 1912, 197) for the determination of gum in syrups. A solution of 20 grms. of the sample in 110 c.c. of water is treated with a mixture of 70 c.c. of 95% alcohol and 10 c.c. of basic lead acetate solution, added gradually, with agitation. After standing for about 1 hour, the mixture is diluted to 200 c.c., allowance being made for the volume of the precipitate, and filtered. 100 c.c. of the filtrate is neutralised with a few drops of acetic acid, evaporated to expel most of the alcohol, then diluted to 100 c.c., the excess of lead precipitated with a small quantity of alum. the solution filtered, and the sugar determined in the usual manner. Sucrose and dextrose can be determined accurately in presence of gum arabic by this method; the results are not quite so good in presence of invert sugar, but are better than those given by the ordinary method and are sufficiently accurate for most purposes.—A. S.

Calcium sulphite; Solubility of—— in water and in sugar solutions. T. van der Linden. Deutsche Zuckerind., 1916, 41, 815. Chem.-Zeit., 1916, 40, Rep., 397.

THE following figures express the quantity of calcium sulphite ($\text{CaSO}_3 \cdot 2\text{H}_2\text{O}$) in mgrms. dissolved by 1 litre of the solvents mentioned at various temperatures between 30° and 100° C.

Solvent.	30° C.	40° C.	50° C.	60° C.	70° C.	80° C.	90° C.	100° C.

manure mixed with peat, and air and carbon dioxide may be mixed with the fermenting mass; the fermentation is stopped by the addition of dilute acid.—B. V. S.

Fertiliser; Manufacture of——. C. F. Pennewell, Sacramento, Cal. U.S. Pat. 1,208,499, Dec. 12, 1916. Date of appl., Aug. 18, 1914.

STABLE manure and a carbohydrate are placed in a container with a perforated base, situated immediately above a second container charged with soil containing nitrifying organisms. About every third day, water is added to the upper vessel at the rate of 2 galls. per ton of the manurial mixture and per ton of soil, and the liquid filters through from the upper to the lower container. The wetted soil is stirred at intervals of about three days, and the moistening and stirring are continued for about ninety days.—E. H. T.

XVII.—SUGARS; STARCHES; GUMS.

Sugars; Determination of—— in presence of gum. G. Savini. Annali Chim. Appl., 1916, 6, 250—255.

THE official Italian and German methods for the determination of sugar in presence of gum, in which the solution is treated with basic lead acetate and the excess of lead precipitated with sodium sulphate, phosphate, or carbonate, do not give accurate results, as the gum is not completely removed by the treatment with lead

The slight solubility of calcium sulphite in water is thus increased by sugar and greatly reduced by calcium sulphate.—A. S.

Zymase and carboxylase in the storage organs of the potato and sugar beet. Bodnar. See XVIII.

PATENTS.

[Sugar] syrup or massecuite; Device for examining a sample of——. Device for taking a sample of syrup or massecuite. W. A. Baldwin, Haiku, Hawaii. U.S. Pats. (A) 1,205,837 and (B) 1,205,838, Nov. 21, 1916. Date of appl., May 17, 1916.

(A) A MICROSCOPE tube is mounted movably in a holder provided with means for trapping a definite quantity of syrup or massecuite between two transparent plates, one of which is fixed in the holder and the other is movable with the microscope tube. The holder may be of tubular form, projecting through the wall of a vacuum pan into the massecuite, and fitted inside with an electric lamp between the inner end, which is closed, and the fixed transparent plate, to illuminate the massecuite between the plates. (B) A plate with a hole in the centre is interposed between, and in close contact with, two transparent plates, one of which is mounted to permit a sliding motion relative to the middle plate for the purpose of opening and closing the central pocket.—J. H. L.

Apparatus for revivifying char. U.S. Pat. 1,207,178. See IIb.

Process of producing a stable fertiliser [from molasses]. U.S. Pat. 1,205,829. See XVI.

XVIII.—FERMENTATION INDUSTRIES.

Zymase and carboxylase in the storage organs of the potato and sugar beet. J. Bodnar. Math. és Termész. Ertesítő, Budapest, 1915, 33, 591—610. Bull. Agric. Intell., 1916, 8, 1092—1093.

Zymase was isolated from stored potatoes and ripe sugar beet; in some cases bacteria were present in the liquid obtained but they did not ferment dextrose in the presence of 2% of toluene. Diseased potatoes yielded an enzyme which produced alcohol from dextrose, but the alcohol thus formed was converted into acetic acid by the action of the soil bacteria present. These bacteria had entered as spores into the enzyme extract of the diseased tubers. As with yeast zymase, the presence of carboxylase was detected in potato and sugar beet zymase. The carboxylase of the potato and sugar beet is much less sensitive than are other enzymes to the effects of high temperatures and various antiseptics.—W. P. S.

Fermentation; Influence of small and short elevations of temperature upon the progress of ———. C. Richet and H. Cardot. Comptes rend., 1916, 163, 954—959.

THE influence of brief exposures to high temperatures on lactic acid fermentation was studied; the progress of the fermentation was judged by the acidity of the solution, the acidity of a fermentation mixture under normal conditions being taken as 100. On exposure for 5 mins. at 57°—58° C. there was a reduction of 53% in the acidity of the solution, and this was maintained during the whole fermentation. Small increases in the length of time for which the raised temperature was applied, had a progressive retarding effect on the fermentation. Thus, in the case of a vigorously fermenting mixture, after an exposure of 1 min. at 58° C. the acidity was 93%, after 1½ min. 74%, after 2 min. 72%, after 2½ mins., 57%, and so on up to 5 mins., when the acidity was only 5%. At a lower temperature, 51° C., applied at the beginning of the fermentation, after an exposure of ½—1 min. the acidity was 86.5%, 1—2 mins. 81.7%, 2—3 mins. 78%, 7—8 min. 65.8%. Repeated exposure of the same fermentation to the elevated temperature caused almost a complete stoppage of the action. Thus, at 54° C., tubes heated once for 5 mins. had an acidity of 77% after 62 hrs. fermentation, while tubes heated five times during that period, had an acidity of only 9%. The human skin, which is the most sensitive part of the body, can bear a temperature of 54° C. for a half-minute, and the experiments indicate that the treatment of wounds with water at 54°—58° C. would delay or prevent pathogenic fermentation.—J. H. J.

Ifines; Analytical discrimination between fermented sweet ——— and mistelles. W. I. Baragiola and C. Godet. Z. anal. Chem., 1916, 55, 561—577.

FROM an investigation of a number of mistelles (wines made by adding alcohol to unfermented musts) and fermented wines, the authors conclude that it is impossible to discriminate between the two classes of products by present analytical methods. Among the values determined were the contents of ether-soluble acids (cp. Blarez, this J., 1903, 928), ammonia and volatile acids, the

lævulose-dextrose ratio (cp. Gautier and Halphen, this J., 1903, 811), and the contents of lactic acid and glycerol.—J. H. L.

Citric acid in wine; Detection and determination of ———. F. Schaffer and E. Gury. Mitt. Geb. Lebensmittel. Hyg., 1915, 6, 247. Chem.-Zeit., 1916, 40, Rep., 425.

THE authors have modified Denigès' method (this J., 1898, 802) so that it can be used for the quantitative determination of citric acid in wine. 25 c.c. of the wine is treated with a slight excess of ammonia, concentrated at least to 10 c.c. on the water-bath, treated with 10 c.c. of a 7% solution of copper sulphate, and again concentrated to 10—15 c.c. After cooling, the solution is diluted to 25 c.c., filtered through a dry filter, and 10 c.c. of the filtrate is treated with 1 c.c. (or 1.5 c.c. in the case of wines with a high content of total solids) of Denigès' mercuric sulphate reagent (5 grms. HgO, 20 c.c. H₂SO₄, and 100 c.c. H₂O), and heated to boiling. The solution is then cooled, filtered, the filter washed with a few c.c. of water, and the solution heated to boiling and oxidised by adding a 1% permanganate solution, drop by drop, until a faint brown coloration is formed, which is destroyed by addition of a few drops of 1% solution of hydrogen peroxide. The precipitated mercury acetonedicarboxylate is separated in a graduated tube by centrifuging for 5 mins. at a speed of 1000—1200 revolutions per minute; the volume of the precipitate in c.c., multiplied by 0.021, gives the quantity of citric acid, in grms., in 1 litre of wine. The precipitate may be identified by washing it with a little cold water, dissolving in 2—3 c.c. of a 10% solution of sodium chloride, and adding a few drops of dilute ferric chloride solution, when a red coloration due to the iron salt of acetonedicarboxylic acid is produced. It was found, in agreement with Kunz (this J., 1915, 974), that natural wines may contain citric acid, and indeed in considerably larger quantities than the 0.008% given as the maximum by Kunz.—A. S. J.

Industrial retting of textile plants by microbiological action. Rossi. See V.

PATENTS.

Temperance stout; Manufacture of ———. E. W. Kuhn, London. Eng. Pat. 12,441, Aug. 30, 1915. (See also Eng. Pats. 1622 of 1908; 18,216, 18,218, and 18,219 of 1909; 11,121 of 1913; this J., 1908, 826; 1910, 1126, 1127; 1914, 659.)

WORT of gravity not exceeding 1016, prepared by ordinary methods, is boiled with hops, cooled, and then fermented in a closed vat so that the pressure of carbon dioxide rises to about 1 atm. by the time the desired alcohol-content (about 0.9%) has been attained. The fermented liquid is chilled to 0°—2° C., filtered, bottled, and pasteurised.—J. H. L.

Brewing of beer. A. Floto, La Serena, Chile. Eng. Pat. 102,470, Aug. 19, 1916. (Appl. No. 11,790 of 1916.)

FERMENTED beer produced from a wort containing a high proportion of extract (c.g., about 12° Balling) and twice the usual quantity of hops, is mixed with an equal volume of unfermented wort of low gravity which has been boiled without hops and cooled. The mixture is subjected to a slow secondary fermentation at a low temperature, to produce a beer of low alcohol-content.—J. H. L.

Spirits; Apparatus for refining potable grain ———. Z. Aronowitz, New York. U.S. Pat. 1,206,495, Nov. 28, 1916. Date of appl., Jan. 11, 1916.

THE apparatus comprises a mixing reservoir and

a feed reservoir and means for supplying spirit from the latter to any one of a series of charcoal filters each of which is so connected with the adjacent ones, and the last with the first, that the spirit can pass through all in turn whichever is made the first in operation. From the last charcoal filter in operation the spirit may be led through a sand filter. Means may be provided for testing the continuous flow of spirit between the filters and for controlling the flow from the last filter in operation. The charcoal filter consists of a metallic vessel fitted with a supporting screen in the lower part, liquid-proof doors for the introduction and removal of charcoal, steam-conducting pipes, inlet and outlet pipes for spirit, an outlet pipe for the passage of spirit to a sand filter, a vapour outlet pipe leading to a condenser, and an air relief pipe; all the outlet pipes are provided with screens to retain solid particles.—J. H. L.

Manufacture of nitrogen compounds [from distillers' spent wash]. U.S. Pat. 1,207,116. See VII.

XIXA.—FOODS.

Amylase in potato tubers: The part played by the —. J. Bodnár and G. Doby. Kiserlet Közlemények, Hungary, 1915, 18, 789—795; 956—968. Bull. Agric. Intell., 1916, 8, 1093—1094.

It was found that no regular relation existed between the sugar content of stored potatoes in a state of rest and the activity of the amylase present; the quantity of reducing sugar (dextrose) did not increase in proportion with the activity of the amylase. On the other hand, a certain relation existed between the activity of the amylase and the proportion of non-reducing sugar (sucrose) and also between this activity and the total quantity of sugar. Thus, with an increase in the activity of the amylase, the proportion of total sugar and of non-reducing sugar also increased. The activity of the amylase is, therefore, of importance, since a high activity indicates that the tubers are rich in sugar or that their respiration is more intense; potatoes with a high sugar-content are liable to rot, and in those having a more intense respiration a greater quantity of the starch is decomposed. (See also this J., 1915, 568, 677.)—W. P. S.

Margarine prepared from hydrogenised fats: Water-content of —. K. Brauer. Z. öffentl. Chem., 1916, 22, 209—216. Z. angew. Chem., 1916, 29, Ref., 492.

HYDROGENISED fats possess the property of "holding" a greater quantity of water than do ordinary fats and oils, and the water in the emulsion is not readily expelled by working the mixture. Margarine prepared from hydrogenised fats frequently contains as much as 20% of water. —W. P. S.

Cocoa powder: Determination of fat in —. Keller. Apoth.-Zeit., 1916, 31, 330. Z. angew. Chem., 1916, 29, Ref., 493.

EXTRACTION with ether in a Soxhlet apparatus for 16 hours is sufficient to extract the whole of the fat from cocoa powder. There is no need to mix the cocoa with sand previous to the extraction, and the addition of sand has the disadvantage that the crude fibre cannot then be determined in the extracted powder. Attention is directed to the fact that theobromine is extracted together with the fat and forms a white deposit on the wall of the extraction flask; the quantity of theo-

bromine thus extracted is small and in most cases may be neglected. If desired, the fat, after weighing, may be dissolved out of the flask with ether and the flask containing the deposit of theobromine re-weighed. In addition to theobromine, the ethereal extract of cocoa contains another basic substance; this yields a gold salt which differs from theobromine-gold chloride in m pt. and gold-content.—W. P. S.

Theobromine and caffeine in cocoa and chocolate: Determination of —. G. Savini. Annali Chim. Appl., 1916, 6, 217—250.

TWELVE grms. of the sample is heated for 10 mins. with 70 c.c. of light petroleum spirit in a 500 c.c. flask, the hot solution is decanted through a filter, and the process repeated twice. The filter paper is transferred to the flask and the residual substance is boiled with 250 c.c. of water and 5 c.c. of 10% sulphuric acid for 1 hour under a reflux condenser. The hot solution is poured off and the flask rinsed with hot water. The acid solution is cooled to about 30° C., made up to 300 c.c., and filtered, 250 c.c. of the filtrate (=10 grms. of sample) is mixed with 10 grms. of sand and excess of magnesia, evaporated to a syrup, and then mixed with a further 8—10 grms. of magnesia which converts it into a dry powder. This is transferred to a flask and treated with 100 c.c. of chloroform, the evaporating dish, etc., being rinsed twice with 2.5 c.c. of hot water, which is added to the chloroform in the flask. After adding 0.25 c.c. of strong ammonia solution, the chloroform is boiled for a $\frac{1}{4}$ hour under a reflux condenser, then decanted through a filter, and the residue again extracted with 100 c.c. of pure chloroform, this operation being repeated until altogether 500 c.c. of chloroform has been used. The chloroform solution is evaporated, and the residue is washed twice, with 5 c.c. of petroleum spirit each time, the liquid being passed through a filter. The residue is then dissolved in a small quantity of boiling water, the solution filtered through the same filter, the insoluble matter washed three times with boiling water, the solution evaporated, and the residue of theobromine and caffeine dried for 1 hour at 100° C. and weighed. —A. S.

Zymase and carboxylase in the storage organs of the potato and sugar beet. Bodnár. See XVIII.

PATENT.

Cooling and drying nuts, cubes and similarly shaped pieces of material for use as food for cattle and other animals, and grain, seed and other materials in bulk: Apparatus for —. G. R. Schueler. Kingston-upon-Hull, Eng. Pat. 102,460, July 26, 1916. (Appl. No. 10,521 of 1916.)

THE apparatus comprises a casing, preferably longer than wide, and open at the top, into which the material is delivered from a hopper. A swinging motion may be imparted to the hopper, to ensure uniform distribution of the material throughout the length of the casing. In the lower part of the casing, and extending throughout its length, are two partitions, sloping downwards from the two longer walls to the floor, and constructed of a number of parallel, overlapping slats, spaced apart. Air pumped into the spaces behind these two partitions escapes between the slats into the main body of the casing and passes upwards through the material. Openings in the floor of the casing, which may be covered and uncovered at will by means of slides, enable the material to be discharged after treatment, and shoots may be provided below the openings.—J. H. L.

XIXB.—WATER PURIFICATION; SANITATION.

Water supply; Decolorisation and removal of manganese from a— H. Klat. Mitt. K. Land. Wasserhyg., 1916, 21, 262—276. Z. angew. Chem., 1916, 29, Ref., 493—494.

THE water supply of the town of Neisse (Silesia) is submitted to the following treatment in order to remove iron and manganese compounds, the presence of the latter rendering the water unfit for use in its natural condition. The water is pumped from the wells into a tank and alum is added in the proportion of 80 grms. per cb.m. of water; the treated water then flows over weirs, where it is aerated, into a series of settling tanks from which the clear water is pumped through gravel filters to remove iron compounds. It is then passed through manganese-permutite filters to remove manganese compounds. The latter filters are regenerated from time to time by means of 2% potassium permanganate solution, and means are provided for washing the gravel and permutite filters. The whole treatment diminishes the quantity of organic matter in the water, besides removing the iron and manganese compounds, and does not increase the hardness. A subsequent filtration through permutite filters containing marble removes any free dissolved carbon dioxide from the water.—W. P. S.

Bac. coli in potable waters; Enumeration of— L. Bourdet. J. Pharm. Chim., 1917, 15, 5—12.

IN France the isolation of *B. coli* from water is effected in phenol broth of varying concentration and at a varying temperature. The various methods are reviewed, and it is considered that a strength of phenol of 1 per 1000 and a temperature of 37° C. are the best conditions. It was found that if more than one tube was inoculated with the same quantity of water, all of them would not necessarily give the same result, owing to the tendency of the *B. coli* to be distributed through the water, not singly, but in groups. When *B. coli* was present, the positive tubes from each quantity of water varied from 66% to 90%. Consequently in making a test, several tubes inoculated with the same quantity of water are examined, the numbers increasing from 3 tubes for 100 c.c. of water to 10 tubes for 1—0.05 c.c. Before any result is taken as indicative of *B. coli*, at least 70% of the tubes for each quantity of water should be positive. The results so obtained are confirmed by taking the positive tubes yielded by the smallest quantity of water, sub-culturing twice in phenol broth, and then making cultures in lactose-peptone-water, peptone-water, and gelatin. In the lactose cultures the indicator is not added until after incubation, when the same number of drops is added to the inoculated tube and to a control uninoculated tube.—J. H. J.

Nicotine sulphate and fish-oil soap sprays; Relationship between the wetting power and efficiency of— L. B. Smith. J. Agric. Res., 1916, 7, 389—399.

THE killing power of the sprays was investigated under field conditions upon peas, spinach, and strawberries against the pea aphid, the spinach aphid, and the red spider, the number of insects being counted before application and two hours afterwards. The peas were sprayed five times and the spinach and strawberry plants once each. The relative wetting powers were determined by the method of Cooper and Nuttall (this J., 1915, 1029). The proportions of the two constituents were varied and in every case 50 gallons of spray was prepared. The results showed that certain concentrated solutions were less satisfactory than weaker solutions, probably owing to chemical

interaction between soap and nicotine resulting in diminished efficiency and wetting power. The proportional efficiency of the mixtures against the three kinds of insects was almost identical. The addition of nicotine sulphate decidedly increased the toxicity of the soap, and *vice versa*, but when more than 4 lb. of soap was used with 10 oz. of the nicotine sulphate to 50 galls. of water, the efficiency fell off from the maximum, 90.8%. The best results were obtained by using 6½—8½ oz. of nicotine sulphate to 5 lb. of soap, and when the amount of sulphate was increased both efficiency and wetting power diminished. With 10 oz. of the sulphate and 1 : 50 soap solution, the maximum efficiency was 75%; and the same figure was obtained for a pure soap solution containing not more than 8 lb. of soap per 50 gallons.—E. H. T.

Influence of small and short elevations of temperature upon the progress of fermentation. Richet and Cardol. See XVIII.

PATENTS.

Sterilisation of liquids and especially of water supplies. L. Linden, London. Eng. Pat. 7205, May 13, 1915.

SEE Fr. Pat. 478,797 of 1915; this J., 1916, 1129.

Regulating and proportioning the feed of chemicals or like substances to water or other fluids. G. G. Earland A. B. Wood, New Orleans, La. Reissue No. 14,230, Dec. 12, 1916. of U.S. Pat. 1,200,324, Oct. 3, 1916. Date of appl. Nov. 1, 1916.

Silicon compound [for water softening] and process of making same. U.S. Pat. 1,205,509. See VII.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Jambul; Some constituents of— M. C. Hart and F. W. Heyl. J. Amer. Chem. Soc., 1916, 38, 2805—2813.

JAMBUL seeds from *Syzygium jambolana* after air-drying contained 8.0% moisture, 40.3%—41.4% starch, 2.3% crude fibre, 2.1% pentosans, 6.3% protein, 2.9% ash, 2.1% dextrin, and 6.0% tannin, the alcohol-soluble carbohydrates consisting of 0.23% sucrose, 2.3% levulose, and 2.1% dextrose. The material obtained by extracting the seeds with wood alcohol at ordinary temperature, when examined by similar methods to those used by Power and Callan (see this J., 1912, 1051; 1913, 849.) for the examination of the hot ethyl alcohol extract, gave very similar results.—T. C.

Lemon grass oil from India. Bull. Imp. Inst., 1916, 14, 381—382.

LEMON grass oil shipped from Cochin is occasionally found to be "insoluble" when submitted to the usual test with 70% alcohol. A sample of oil distilled from "white-stemmed" lemon grass (*Cymbopogon flexuosus*, Stapf), examined in 1913, resembled citronella oil rather than a true lemon grass oil (this J., 1914, 805). A further specimen has therefore been obtained, and its source identified as *C. flexuosus*, Stapf, f. *albescens*, a colour variety of ordinary Cochin lemon grass. The following are the constants determined for this specimen, and for the earlier specimen respectively:—Sp.gr. at 15/15° C., 0.915, 0.909; refra

tion (100 mm., 22° C.), too dark, $-10^{\circ} 50'$; aldehydes, 81.9%; solubility (80% alcohol) sol. in 0.7 vol., turbid in 4.5 vols., sol. in 0.8 vol., turbid in 4 vols.; (70% alcohol), not sol. in 5 vols., at but 15° C., sol. in 2.5 vols., at 20° C., not sol. in 5 vols. The new sample is therefore a normal lemon grass oil, and hence "insolubility" is not due to inclusion of other grasses. It is probably due to distillation being carried too far.—E. W. L.

Essential oil of Sherungdu tubers. II. Bull. Imp. Inst., 1916, 14, 378—381. (Cf. this J., 1915, 511.)

A CONSIGNMENT of tubers from the Transvaal, weighing 235 lb., was received in August, 1915. These contained moisture, 74.7%, as compared with 42.2 and 25% in earlier samples. Distillation in the laboratory, and also under factory conditions, gave respectively 0.55 and 0.45% of oil calculated on original tubers. Examination of the factory-distilled oil gave:—Spgr. at 15°/15° C., 0.924; rotation (100 mm.) at 22° C., $+26^{\circ} 42'$; acid value, 1.0; ester value, before acetylation, 11.5, after acetylation, 33.6. On re-distillation the following fractions were obtained: 160°—195° C., 44; 195°—270° C., 26; residue (chiefly ketone and sesquiterpene), 30%. The odour of the oil as obtained by distillation is unpleasant, that of the refined oil was not much valued by perfumers, etc. At best the oil would only be useful as a substitute for spike lavender oil, and its production would therefore be unprofitable. The high-boiling constituents are comparatively odourless, and the perfume of the oil therefore lacks persistence.—E. W. L.

Cassia oil; Removal of lead from—. Ber. von Schimmel und Co., Apr. to Oct., 1916. Z. angew. Chem., 1916, 29, Ref., 518.

100 GRMS. of the oil is shaken vigorously and repeatedly with 1 gm. of powdered tartaric acid, and filtered from the flocculent precipitate. The colour of the oil is improved by the treatment, and practically no separation of crystals occurs at the zone of contact of the aqueous and oily layers in the subsequent determination of the aldehydes.—A. S.

Ionone; Manufacture of—. H. F. Slack. Perf. and Essent. Oil Rec., 1916, 7, 389—391.

WHEN lemongrass oil is distilled with steam the early and later fractions contain only a small percentage of citral, whilst intermediate fractions contain up to 91% and are much more suitable for the manufacture of ionone than the unrectified oil. The condensation agent, used in condensing, the citral with acetone should be in solution, as insoluble condensation agents, such as sodamide, cause local overheating with consequent production of tarry and resinous matters. The yield and quality of the condensation product are much improved by carrying out the condensation in presence of a diluting agent, the best result being obtained by employing excess of acetone as diluting agent; five parts of acetone to one part of citral is a suitable proportion. Sodium ethoxide is a much better condensation agent than either sodamide or barium hydroxide, the best proportion being one part of a 5% solution of sodium ethoxide in absolute alcohol to two parts of citral. During condensation the temperature must be kept as low as possible, and prolonged contact with the alkaline condensation agent must be avoided. Immediately after condensation the excess of acetone is removed by rapidly washing with water, and the unchanged citral removed by distilling with steam. The residual pseudo-ionone is converted into ionone by boiling 100 parts with 15 parts of concentrated sulphuric acid, 500 parts of

glycerol, and 500 parts of water for six hours. The use of 50% sulphuric acid in the cold instead of dilute acid leads to increased amounts of tarry products. The product requires to be repeatedly rectified to give ionone of the highest grade, the distillation being carried out as rapidly as possible to avoid loss by resinification. The final product is greatly improved by passing a rapid current of steam through it, followed by a current of air for several hours.—T. C.

Acetic ester of tribromo-tertiary-butyl alcohol or brometone acetic ester. Studies on derivatives of trihalogenotertiarybutyl alcohols. I. T. P. Aldrich and C. P. Beckwith. J. Amer. Chem. Soc., 1916, 38, 2740—2746.

TRICHLORO- and tribromo-tertiary butyl alcohols ("chlorotone" and "brometone") are known to possess pronounced sedative, hypnotic, and anæsthetic properties, both local and general. Brometone is considered to have more marked sedative, but less pronounced hypnotic and anæsthetic properties. From their reactions they may be regarded as trihalides of ortho- α -hydroxy-isobutyric acid. The acetic ester of tribromo-tertiary butyl alcohol can be prepared from acetyl chloride or bromide and the alcohol, or by means of acetic anhydride and fused sodium acetate. When recrystallised from alcohol it melts at 43—44° C. (uncorr.), is extremely soluble in most organic solvents but practically insoluble in water. It is not readily saponified by boiling water or dilute acid. When saponified the alcohol is decomposed. Saponification takes place quickly with hot concentrated nitric acid. The ester is volatile in the air and in steam, but less readily than chlorotone or brometone. Unlike the parent alcohols, the ester is stable to warm 5—10% caustic alkali solutions. An account is given of the pharmacological action of this and other esters of chlorotone or brometone. (Compare Woffenstein and others, this J., 1916, 328.)—F. C.

Amidines; Synthesis of— from cyanamides by means of the Grignard reagent. R. Adams and C. H. Beebe. J. Amer. Chem. Soc., 1916, 38, 2768—2772.

DIBENZYL-CYANAMIDE on treatment with the Grignard reagent yields first a magnesium halide addition compound, which on treatment with dilute acid is converted into a salt of a substituted amidine. Thus dibenzylcyanamide with ethyl, phenyl, and tolyl magnesium halides and subsequent treatment with hydrochloric acid, yields the hydrochlorides of dibenzylpropionamidinium, m.p. 204°—204.5° C., of dibenzylbenzamidinium, m.p. 211.5° C., and of dibenzyltoluylamidinium respectively. The free amidines obtained by treating these salts with alkalis are very soluble oils or low melting solids which can only be purified with difficulty.—T. C.

PATENT.

Ethylenglycol; Production of—. A. Hough, Lavigne, Quebec. U.S. Pat. 1,206,222, Nov. 28, 1916. Date of appl., Feb. 21, 1914.

ETHYL alcohol vapour is brought into contact with thin layers of aluminium sulphate upon inert material, at a high temperature (350°—400° C.) and in the absence of air, so as to remove the combined oxygen without forming aldehydes. The resulting ethylene is converted into ethylene dichloride, and the chlorine in the latter is replaced by hydroxyl by means of ferric oxide. The ferric chloride formed in the reaction is oxidised, and the resulting ferric oxide and chlorine are used for the treatment of further quantities of ethylene.—C.A.M.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

PATENTS.

Cinematograph film; Renovated —. A. P. H. Trivelli, The Hague, Netherlands. U.S. Pat. 1,205,822, Nov. 21, 1916. Date of appl., Aug. 3, 1916.

A RENOVATED cinematograph film consists of a film coated with a closely adherent layer of transparent flexible varnish containing a salt of a resin acid, a cellulose ester, and a drying oil, and having practically the same coefficient of refraction as the original film. (See also Eng. Pat. 7956 of 1915; this J., 1916, 751.)

Colour photography; Multicolour screens for —. I. Kitsee, Philadelphia, Pa. U.S. Pat. 1,206,000, Nov. 28, 1916. Date of appl., Apr. 8, 1915.

MINUTE coloured particles, suitable for the formation of multicolour screens, are obtained by spraying a coloured solution of a suitable solid through an atmosphere containing a substance, such as formaldehyde, which coagulates the solid and prevents coalescence of the particles.—B. V. S.

XXII.—EXPLOSIVES; MATCHES.

Explosives; Simple tests for —. A. Stettbacher. Z. ges. Schiess- u. Sprengstoffw., 1916, 11, 249—251. Z. angew. Chem., 1916, 29, Ref., 495.

IN order to make rapid tests of the properties of an explosive by means of simple apparatus, it is a great advantage to have an arrangement whereby explosive force and scattering or detonating effect can be measured simultaneously. The method suggested is to pack tightly about 50 grms. of the explosive in a thick-walled nickel crucible which is placed on a plate of soft iron, 6 to 8 mm. thick, and supported on a stand. After bringing about explosion, the detonating effect is measured by the depth of the impression made in the iron plate by the crucible, by the disintegration of the surface, and the amount of scaling. The total energy of the explosion is measured by the bulging and the distortion of the metal plate.—J. N. P.

Pentaerythritol and its nitric ester. A. Stettbacher. Z. ges. Schiess- u. Sprengstoffw., 1916, 11, 182—181. Z. angew. Chem., 1916, 29, Ref., 495—496.

PENTAERYTHRITOL $C(CH_2OH)_4$ gives on nitration a compound which combines the explosive properties of nitromannitol and nitroglycerin, while being free from the disadvantages of these. A method of preparation described by Tollens enables pentaerythritol to be produced in large quantities and purified cheaply. In the form of its tetranitrate the compound is suitable for use in primers, percussion caps, and detonators. In consequence of the linking of the ester groups to a central carbon atom, the nitrate is particularly stable, less sensitive than nitromannitol, but more sensitive than tetranitromethylaniline. As shown by calorific measurements, it possesses a greater decomposition energy than the materials hitherto used for initiating explosions. The preparation of the compound is described in Ger. Pat. 245,025. (See also Eng. Pat. 20,281 of 1891; this J., 1895, 66.)—J. N. P.

Ammonium chlorate; Stability of —. J. Gelhaar. Z. ges. Schiess- u. Sprengstoffw., 1916, 11, 166—167. Z. angew. Chem., 1916, 29, Ref., 496—497.

AN investigation was made of the properties of

ammonium chlorate in the solid state and in aqueous solution. At ordinary temperatures, 3 grms. of the salt exposed in a thin layer to air lost 80% of its weight as gaseous products in 7 weeks. The nitrogen was partly oxidised to nitric acid. At 40° C., spontaneous decomposition took place after 11 hours. 0.5 gm. heated to 70° C. decomposed after 45 mins., 0.1 gm. heated to 90° C. after 10 mins., and at 100° C. after 3.5 mins. In solution, the decomposition took place somewhat more slowly. The dry salt was detonated by a hammer of 2 kilos, falling from a height of 15 cm. In the lead block test, an indentation of 25 t. c.c. was obtained on detonation.—J. N. P.

PATENTS.

Blasting cartridges. W. Weber, Hayingen, Germany. Eng. Pat. 12,463, Aug. 10, 1915. Addition to Eng. Pat. 8606, June 10, 1915.

BLASTING cartridges made as described in Eng. Pat. 8606 of 1915 (see U.S. Pat. 1,157,270; this J., 1916, 276) may contain several combustible metallic powders instead of a single powder, the mixture being placed in a bag, with or without the addition of amorphous carbon or an organic substance, which may have great absorptive capacity for liquid air.—C. A. M.

Explosive containing nitroglycerin. W. Cospy, San Francisco, Cal. U.S. Pat. 1,205,516, Nov. 21, 1916. Date of appl., July 8, 1916.

NITROGLYCERIN (80%) is incorporated with tetrachloroethene (tetrachloroethylene) or a mixture of tetrachloroethene with 20% of tetrachloromethane (carbon tetrachloride).—C. A. M.

Glycol dinirate; Process of making — for explosive uses. A. Hough, Choisy, Quebec. U.S. Pat. 1,206,223, Nov. 28, 1916. Date of appl., Oct. 22, 1911.

GLYCOL (1 part) is nitrated with a mixture (7 parts) of nitric and sulphuric acids containing not less than 93% nor more than 96% of total acids. The nitration mixture may contain from 35 to 36% of nitric acid and 58 to 59% of sulphuric acid, and special claim is made for a mixture containing 35.1% of nitric acid, 59% of sulphuric acid, and 5.85% of water.—C. A. M.

Explosive charge for shells and the like. E. Stern, Hanover. Ger. Pat. 291,811, Aug. 1, 1915.

A FILLING recommended for shells and other projectiles consists of silicon chloride in conjunction with explosives. A violent reaction takes place between the silicon chloride and the water vapour which is produced by some explosives.—J. N. P.

Match and process of making the same. D. A. Venot and L. P. Chasseigne, Pantin, France. U.S. Pat. 1,208,111, Dec. 12, 1916. Date of appl., Aug. 4, 1911. Renewed May 1, 1916.

SEE Fr. Pat. 430,711 of 1910; this J., 1911, 1111.

Manufacture of nitro compounds. Eng. Pat. 102,216. See 111.

XXIII.—ANALYSIS.

Sulphonaphthalein series of indicators and the quinone-phenolate theory. H. A. Lubs and S. F. Acree. J. Amer. Chem. Soc., 1916, 38, 2772—2784.

SULPHONEPHTHALEINS (see this J., 1915, 1226;

1916, 980) containing no negative bromo or nitro group in the phenol residues, when in solution as free acid or as monobasic salt, are yellow to orange in colour, the colour and conductivities indicating that they exist largely in the quinonoid form. On titration with alkali there is an intense colour change when 0.85 mol. to 0.98 mol. of alkali has been added, with formation of the dibasic salt. Solutions of sulphonephthaleins containing negative bromo or nitro groups in the phenol residues have high molecular conductivities and low P_H ranges, indicating considerable ionisation of the phenol residue, and these solutions exhibit more or less the colour of the dibasic salts. Addition of mineral acids to such solutions suppresses the ionisation of the phenol group and changes the intense colour characteristic of the dibasic salts into the fainter yellow or orange of the quinone group. The free sulphonephthaleins and the monobasic salts give absorption spectra containing a yellow band characteristic of the quinones, whilst the dibasic salts have a deep band in place of the yellow band, indicating that the quinone group as such disappears due to combination with the phenolate anion to form a complex quinone-phenolate group. By substituting bromo, nitro, methyl, isopropyl, amino and other groups in the benzenesulphonic acid group and especially in the phenol residue, the ionisation constants of these groups may be greatly changed and indicators of a wide range may be thus obtained. The phenol-, thymol- and cresol-sulphonephthaleins and their bromo derivatives are highly satisfactory indicators.—T. C.

Trade Report.

Prohibited exports. Order in Council, Jan. 15, 1917.

THE following headings have been removed from the Royal Proclamation of May 10th, 1916 (see this J., 1916, 620): ¹Alcohol, methylic. ¹Amyl acetate. ³Barium sulphate. The following headings are added: ³Bone black. ¹Alcohol, methylic, and its esters. ¹Amyl acetate and other amyl esters. ²Barium sulphate.

Chemical and medical glass, etc. Regulations for trading. See VIII.

Book Received.

THE CENTRAL. Vol. XIII. No. 39. SPECIAL CHEMICAL DEPARTMENT NUMBER. Percival Jones, Ltd., Birmingham.

THIS issue of "The Central," which is the journal of the old students of the Central Technical College, contains a brief record of some of the work done in the College under the leadership of Professor Armstrong during the years 1884 to 1914. The subjects dealt with are "Stereochemistry and crystallography," by W. J. Pope. "A reform in education," by W. M. Heller. "Early physico-chemical work at the Central," by H. Crompton. "On chemical change," by T. M. Lowry. "The chemistry of camphor," by A. Lapworth. "Crystallography," by H. A. Miers. "The naphthalene research," by W. P. Wynne. "Biological investigations," by J. V. Eyre. The number concludes with some notes on the origin and development of the chemical school at the Central, by Prof. Armstrong, and a brief account of the careers of the students who have worked under him at the College.

Official Notices.

REPORTS OF THE PROGRESS OF APPLIED CHEMISTRY.

Owing to unforeseen delays in the receipt of the manuscript of certain sections of these Reports, it is regretted that the publication of the first volume is unavoidably postponed until March.

CROSS AND BEVAN ESSAY PRIZE OF £20 AND LATHAM RESEARCH GRANT OF £300.

The Council have pleasure in announcing that a gift of £20 has been made by Messrs. Cross and Bevan as a prize for an essay on "The Inter-connection of Economic Botany and Chemical Industry."

A further sum of £300 has also been presented by their friend, Mr. T. P. Latham, of Weybridge, to be paid in three annual instalments to such one of the competing essayists as may be judged to be of conspicuous ability, as a grant towards his expenses, on the condition that he apply himself, during three years, to research of approved character on a subject cognate with that discussed in his essay.

The immediate object of the donors is to promote the study of economic botany with special reference to its bearing on chemical industry, giving the widest possible interpretation of the relationship.

They desire, under the auspices of the Society, to assist in forming public opinion in this direction and to discover and further the career of a student of promise who may wish to devote himself to work in such a field.

The Essay Prize will be open to all members of the Society who are British subjects. The Research Grant will be limited to competitors under 25 years of age at the time of sending in the essay.

Essays are to be submitted to the Council of the Society not later than the close of the year 1917. The awards will be made promptly. Neither the prize nor the first grant will be given unless the essayist or essayists shall be deemed to have real merit. The Latham Research Student will be required to submit a report at the close of each year, to satisfy the Council that he has made and is likely to make proper use of the grant.

London Section.

Meeting held at Burlington House on Monday, January 15th, 1917.

MR. A. B. LING IN THE CHAIR.

A NEW METHOD OF EXTRACTING THE VAPOROUS CONSTITUENTS FROM COAL GAS.

BY R. LESSING, PH.D.

The recovery of benzol from coal gas is a problem which has engaged the attention of the carbonising industry for the last 50 years. A good account of its early development, in which men like Cusiter, H. Caro, J. Hardman, G. E. Davis, and F. Carvès appear as pioneers, is given in Lunge's "Coal Tar and Ammonia."

The process was first practised in the English "carbonising" works, then taken up by the by-product coke oven industry, and reintroduced into this country by Continental coke-oven builders.

The gas industry became interested in the recovery of benzol from gas a few years ago as a

means of augmenting the supply of motor fuel, but the statutory requirements of illuminating power stood in the way of its adoption on an appreciable scale.

Whilst the way had been paved, by the fixing in a few individual cases of a calorific standard—the more rational one in view of the growing importance of coal gas as a heating agent—it took the stern demands made by the present War to sweep away old traditions and idiosyncrasies and to make the valuation of gas on a calorific basis more general, or, at any rate, indemnify gas undertakings against deficiencies in illuminating power where they are caused by the extraction of benzol and toluol for munitions purposes. Under these conditions, created by the War, benzol extraction was taken up by many gas undertakings and to an increased extent by coke-oven works which had not previously practised it.

The principle of the process is practically the same in all plants although they may differ in details of design and working. It consists of scrubbing or washing the gas with an absorbent oil and subsequently distilling the absorbed hydrocarbons from the "benzolised" oil and returning the "debenzolised oil," after cooling, to the scrubbers or washers. The scrubbers used are in the main of three types: tower scrubbers filled with more or less efficient packing material; mechanical washers of the horizontal or vertical type; and bubbling washers of the Livesey type. As to stills, a great many varieties of design are in use, many of which are capable of improvement by the application of a more thorough study of the physico-chemical laws involved. Oils from coal tar, blast furnace tar, shale, and petroleum are being used as absorbents, the most important ones being creosote oil, green oil, and gas oil. Undistilled tar is also used as originally proposed by Fricllaender and Quaglio (Eng. Pat. No. 4888, April 1, 1887) and in that case the distilling plant can be dispensed with as fresh tar is produced at the works and the benzolised tar is worked up by the tar distiller. As the boiling range of tar is a very wide one it may act at the same time as a scrubbing and carburetting agent, and to low absorbing efficiency, on account of high water or carbon contents, is frequently added the risk of the gas picking up additional naphthalene from the tar.

The adoption of a process which dispenses with a distilling plant in preference to the more efficient method of washing with oil in a continuous cycle, exemplifies a certain justifiable reluctance on the part of managers of small or medium-sized gas works to add the duties of chemical manufacturers to their manifold responsibilities. It was, therefore, considered desirable to devise a process of benzol recovery which should combine extreme simplicity in design and working of the plant with a fair degree of efficiency.

The use of a "dry" scrubber filled with a solid absorbent material which would strip benzol from the gas without the employment of running wash oil and from which the volatile products could be removed by steam distillation *in situ*, appeared to offer a solution of the problem.

I had observed a number of years ago in the analysis of spent oxide that it was difficult to obtain constant figures when endeavouring to estimate its moisture by passing a current of dry coal gas over it. I explained these results, even at that time, by the absorption of hydrocarbons and carbon disulphide in the gas by the free sulphur and particularly by the tarry matter in the spent oxide. On searching the literature I find that a similar observation had been made

with American spent oxide by Goodno (Gas World, 1893, 18, 296). However, I did not consider spent oxide a suitable material either for the absorption or for the distillation phase of the process. This opinion has since been confirmed with regard to the absorption of carbon disulphide on the practical scale by Teune in experiments carried out at the Amsterdam Gas Works (J. Gas Lighting, 1915, 130, 331).

It appeared to be necessary to find a material of greater and more definite absorptive power, and one which should offer considerably less back pressure than spent oxide would do and not be subject to chemical side-reactions.

It was found that the illuminating power of coal gas could be greatly reduced by passing it through a tube charged with pitch crushed to the size of a pea. It was, however, observed that the sharp-edged pieces became rounded, and that the pitch started "squatting" and finally "running" as soon as its viscosity had decreased sufficiently by the absorption of its solvents from the gas. This showed that it would be impossible to pack a scrubber with it, as it would tend to consolidate

allowing it to remain quiescent, and indeed to behave as a solid, as far as contact with the gas and the production of back pressure is concerned. The absorbed compounds can be liberated from their solution in the oil, *in situ*, by steam distillation, and to this phase of the steaming process apply the same considerations regarding the exposure of a large surface and avoidance of back pressure, as to the scrubbing period.

On this basis the following process was devised:—The gas is passed through a closed vessel which contains porous material soaked in a suitable oil—for instance, green oil or gas oil. The inert material may consist of broken highly porous brick or, preferably, of moulded pieces of definite shape, volume, weight, and available surface. The vaporous compounds in the gas in which the oil is soluble, *i.e.*, the hydrocarbons and organic sulphur compounds, which when isolated, are liquid at ordinary temperature, are absorbed. When the oil has taken up the required amount of the substance to be extracted, which will depend on the quantity and surface of the absorbing agent, the velocity and volume of the

FIG. 1.

and block the passages, even if the temperature were kept low enough for the original pitch to remain rigid.

It was, therefore, necessary to supply a rigid support for the absorbent material. Whilst pitch had been selected on account of the high viscosity, both of itself and its solution in carbon disulphide, benzol, toluol, etc., it was found in the course of further experiments that oils of fairly low viscosity could be incorporated into highly porous inert materials without being unduly thinned or washed out by the solvent vapours from the gas. Whilst, therefore, in the usual methods of washing or scrubbing gas with oils the gas is caused to bubble through a body or pass through a shower or rain of washing liquid, it was found possible to charge scrubbers with oil carried on an inert and rigid support,

gas, the temperature and degree of its saturation, the mutual solubility of the vapours and the absorbing oil, and the vapour pressure of the solution formed, the gas inlet and outlet valves are closed, the gas current being directed into the second vessel of the series. Steam is then blown through the material, carrying the vapours of the absorbed compounds with it to the water-cooled condenser and finally to a receiver fitted with overflow pipes for water and crude benzol respectively. It is advisable to provide the "scrubber-still" with a jacket to avoid the condensation of steam, particularly on the walls. It is, however, not necessary to raise the whole of the inert carrying material to the temperature of distillation. As the oil forms a very thin film and is, therefore, completely exposed to the passing steam, the

volatile matter dissolved in it is distilled off before the non-conducting support is raised throughout its mass to the same temperature.

When the distillation is finished the steam is shut off and the vessel is cooled by passing water through the jacket, and is then ready for the next scrubbing period.

By employing three or more sets of "scrubber-stills" they can be worked in rotation, a definite schedule being arranged for the three periods of scrubbing, steaming, and cooling.

It will be seen that the labour involved is restricted to the manipulation of valves for changing over from gas to steam and *vice versa*, and to the collection of the distillate. As there are no pumps or other moving parts involved in the process, nor adjustments of the flow of oil, the plant does not require any attention except for the change-over from one period to another. The steaming is to be done only once in 24 hours, or at even longer intervals, and occupies only a fraction of the time available for scrubbing. The ground-space required is, if anything, smaller than that occupied by the usual combination of scrubbing and distilling plant. Losses of oil are restricted to the portion distilled off with the steam, particularly if superheated steam is used. In places where the crude benzol is fractionated this oil can be returned in the form of residue. Elsewhere it is replaced by fresh oil, which is occasionally introduced through the top of the scrubber and is allowed to soak into the material on its way to the bottom, where any excess is drawn off through drain-cocks.

The efficiency of scrubbing or washing in the customary manner depends upon constantly breaking up the oil into small drops or thin films, in order to expose new surfaces, and likewise upon deflecting the gas currents at short and frequent intervals to avoid the formation of inactive cores in bubbles or streams. In the proposed method all the oil is exposed in a thin film into the body of which the gas can readily diffuse and which, therefore, does not require breaking up or turning over.

Thickening of the wash oil in ordinary scrubbers is a disadvantage on account of the less intimate contact caused by a rise in viscosity. In this process, provided the solubility is not impaired, the thickening of the oil is rather an advantage, as a more viscous oil is more readily retained by the porous material than a thinner one; whilst the area of the oil film exposed to the gas and steam respectively remains unaltered.

The interaction of gas and oil further depends on time-contact. Assuming equal rates of gas passage and equal scrubbing surfaces of a "dry" scrubber and an "irrigated" scrubber a certain volume of gas would remain in contact with oil for about the same time in both cases. On the other hand the oil in the "dry" scrubber will remain in contact with gas throughout the whole scrubbing period, whilst the contact of each particle of oil passing through the "irrigated" scrubber or through a washer depends on the rate of flow, which varies in wide limits with different constructions, but it is always considerably shorter than that of the quiescent body of oil locked up in the "dry" scrubber. Consequently the oil in the latter has a chance to saturate itself with the vapours from the gas to the maximum limit of the permissible vapour pressure of the solution formed. The latter is more concentrated near the gas inlet than towards the outlet, and if the vessel is divided into compartments, or several vessels are arranged in series, one will be completely saturated whilst the following ones act as check vessels and it is only necessary to steam the completely saturated vessel whilst the second and third become Nos. 1 and 2 respectively, in the series.

Pending the elaboration and thorough testing of the process on a works scale, I have constructed an experimental apparatus for analytical and

research purposes based on the same principle, which has proved useful in this class of work during the last two years. The need for a simple and reliable method of controlling oil washing operations has been expressed on various occasions lately, and I have, therefore, been encouraged by the Ministry of Munitions to publish the details.

None of the purely chemical methods which have been proposed from time to time has been found satisfactory for the control of benzol extraction plants in gas and coke works. The most accurate physical method is probably the freezing out of the condensable hydrocarbons. This was proposed by St. Claire Deville (J. des Usines à Gaz, 1889), who extracted benzol and its homologues by passing from 10 to 20 cub. ft. of gas through glass coils placed in a freezing mixture at -22°C . and weighing the condensate. He also determined the quantity of benzol required to saturate the gas at that temperature by further cooling it to -70°C .

Lebeau and Damiens (Comptes. Rendus, 1913, 156, 144, 325) devised a method for the fractional distillation of liquefied coal gas on the lines of the researches of Ramsay and Travers. This method was amplified by Burrell, Seibert, and Robertson (U.S. Bureau of Mines Tech. Paper 104, 1915).

Whilst exceedingly useful for the estimation of the permanent gases and the total quantity of vapours—if that distinction be permitted—these methods deal with quantities too small to allow of a separation of the vapour mixture into its components. These are, therefore, lumped together into one figure representing "compounds having an inappreciable vapour-pressure at -78°C ." and their volume in uncondensed form amounts to only about 1.5% of the total. Their further treatment is, therefore, out of the question.

H. F. Coward and F. Bailey (Manchester Lit. and Phil. Soc., 1916, XXIV.) pass a current of gas through a tube immersed in a mixture of solid CO_2 and ether for the purpose of estimating the illuminating power of the stripped gas on the lines of St. Claire Deville's experiments.

Whilst all these methods are very valuable for purely research purposes the apparatus is complicated and costly, and requires skilled manipulators; besides, the quantities of liquid hydrocarbons obtainable in reasonable time are too small for practical purposes.

The method most widely adopted for works purposes is the passage of gas through a train of wash bottles charged with tar oils or petroleum oils of various description. The gas is passed at the rate of about 1 cub. ft. per hour. The first bottle in the series is emptied twice a day, charged with fresh oil and placed at the end. The oil from all the bottles is collected and distilled in a metal retort, with the aid of steam for the fractions above 130°C . On account of the back-pressure caused by the oil and the low scrubbing efficiency of most types of wash bottles, the rate of gas cannot be increased, and a complete test of 100 cub. ft. of gas consequently takes practically 5 days.

On account of the bubbling the stream is not constant, and if the gas is to be tested for calorific value or illuminating power it has to be collected in a holder to obtain a steady flame. At best, absorption in wash bottles is attended by the drawbacks of rubber connections and leaks in stoppers.

The method described below overcomes these difficulties. Figure 1 is a photographic view, and Figure 2 is a diagrammatic section of the apparatus. The container, A, is filled with the oil-soaked inert material, C, which rests on a perforated bottom, B, and exerts only a negligible back-pressure to the gas. The gas to be tested enters through stop-cock, D, passes downwards through the material, and through the gas outlet, E, into the gas meter. I prefer to arrange the

FIG. 2.

gas meter after the scrubber in order to avoid condensation or extraction of vapours in the meter. In most cases it is also more convenient to relate the results to totally extracted gas as a basis. The use of rubber tubing should be avoided as far as possible.

After leaving the meter the gas may be used for any further chemical or physical examination required. Or else it may be burned and then indicates, by its almost entirely blue flame, the satisfactory working of the scrubber. It burns with a perfectly steady flame, and if the burner is arranged on the lines of a jet photometer the length of flame, when compared with that of the unstripped gas, will give a direct, though somewhat empirical, measurement of the extracted hydrocarbons. Only the inner cone of the flame shows a small amount of luminosity, which is due to the non-condensable illuminants, such as ethylene, propylene, and acetylene, and to the small amount of vapour due to the vapour pressure of the solution formed, which is constant for any given temperature.

The container, A, is surrounded by a jacket, G, which is provided with a gauge, H, and drain-cock, J, and is filled with water during the scrubbing period. The gas is passed through the apparatus at the rate of about 5 cub. ft. per hour, and about 100 cub. ft. are used for one experiment. This will, therefore, cover a period of 20 hours, during which the apparatus does not require any attention at all.

Stop-cocks, E and D, are then closed, K is opened and the water run out through drain-cock, J, until it fills only about one-third of the jacket. A gas ring burner, R, is then lit and steam is raised in the jacket, the excess steam escaping through the condenser O. When the water is well boiling K is shut and stopcocks, M and X, are opened, the pressure having been relieved from time to time through X. At the same time the Bunsen burner,

S, is lit. The steam raised in the jacket passes now through the super-heater coil, L, and stop-cock, M, to the bottom of the inner container and up through the absorbent material. The steam and vapours pass through X and condenser, O, and are collected in a graduated separating funnel clamped to the stand under O. P is the inlet for the cooling water and Q its overflow. The charging hole, T, through which the material is put into the apparatus, is closed by a screw-cap. Any water condensing in the vessel or surplus oil is drawn off through drain-cock F.

The steam distillation, including heating up, takes from 1 hour to 1½ hours, and is usually carried on until the absorbed naphthalene is distilled over. To avoid blockages in the condenser it is advisable to allow the cooling water to get hot before the naphthalene stage is reached.

By drawing off the hot water and running cold water through the jacket the apparatus cools rapidly and is then ready for scrubbing again; so that the complete cycle of operations can be carried out within 24 hours and therefore daily tests can be made.

According to the vapour contents of the gas being tested, from 100 to 200 c.c. of steam distillate is obtained. This is separated from the water, measured, and further examined by distillation. In most cases the estimation of benzene and toluene is the principal object. For this purpose H. G. Colman's method of fractionation and final distillation of mixtures with pure benzene, toluene, or xylene is followed.

Apart from the estimation of benzene and toluene considerable interest attaches to the examination of the lower and higher fractions. Even one day's product yields a fair amount of material for the closer examination of the extract from the gas, and a week's supply will suffice for quite considerable research.

It should be remembered that the term "benzol" in this connection refers to a mixture of a number of hydrocarbons and sulphur compounds, and may include paraffins, di-olefines, and naphthalene. Whilst at the moment the production of pure benzene and toluene is in the focus of interest on account of the supply of raw materials for explosives and dyestuffs, the identification and quantitative relation of the other components of the mixture of vapours in coal gas is of the highest importance.

The extraction of condensible hydrocarbons from coal gas has probably come to stay, and will form a valuable source of raw materials for chemicals and motor fuel purposes. As long as the present policy of gas undertakings—of supplying a more or less considerable percentage of inert gases with their product—continues, this deadweight must be compensated by enriching the gas with compounds of greater molecular weight and higher carbon: hydrogen ratio, and consequently higher calorific and illuminating value.

By a study of the compounds of this kind "naturally" present in the gas when leaving the retorts—or the superheater in the case of water gas—it will be found which of them are, economically, the most and which the least important. It will probably pay to extract the gas exhaustively, and re-incorporate with it the hydrocarbons having a lower value for others purposes; or else replace the extract or part of it by cheaper-grade petroleum distillates or cracked spirits.

However, signs are not wanting which point to the possibility of obtaining high makes of gas from coal without the necessity of dilution with nitrogen or carbon dioxide, in the not far distant future. If this comes to pass it will be possible to extract all condensible compounds from the gas and still supply a commodity which in calorific value is far superior to that of the present day.

But even now the detailed examination of the condensible hydrocarbons, beyond their customary

inclusion in " C_nH_m " or "illuminants," of which they form the smaller portion, is essential.

It should be realised that the value of coal gas as a commodity depends in the first instance on its chemical composition. The expression of the aggregate of its constituents and their properties, merely by a composite physical value such as the heating or illuminating power, may be convenient and necessary for the business relations of gas works with their consumers. But, for the study of the mechanism of carbonization and after-treatment of the gas and the wider aspects of the fuel problem a more extensive application of analysis to coal gas, and particularly to its smaller but not less important constituents, is highly necessary.

It is hoped that this method will be found useful in this connection. In the control of benzol extraction plants it has been found capable of discriminating between the hydrocarbons present before and after scrubbing. As is only to be expected it has been found that a large proportion of the naphtha scrubbed out from the gas consists of higher fractions which are of less immediate importance than benzene and toluene, which are frequently allowed to go forward with the gas. The daily control of the extracting efficiency and a closer study of oils and solutions (benzolised oils) at the temperatures concerned is highly desirable.

It should be added that conversely the method is adaptable for the comparative testing of various oils against gases carrying known percentages of vapours both as regards their absorbing capacities and their behaviour on steam distillation.

In conclusion I wish to express my thanks to the Ministry of Munitions for their permission to publish this paper, and to Messrs. Alexander Wright & Co., Ltd., the makers of the apparatus.

THE VULCANISATION OF RUBBER BY AGENTS OTHER THAN SULPHUR.*

BY HENRY P. STEVENS, M.A., F.I.C.

A remarkable series of papers has recently been published by I. I. Ostromyslenski,† in certain of which he claims to have substituted successfully certain nitro compounds and peroxides for sulphur in the vulcanising process. The work, however, is of a superficial character, regarded from the standpoint of the rubber technologist. The proportions are given of a number of mixes containing the above-mentioned substances. These were cured in an autoclave or steam press at various pressures for varying periods. The vulcanisate is variously described as incompletely, completely, or over vulcanised, but there is little or no indication of the physical properties of the product, nor are figures given which would enable a comparison to be

drawn between the physical properties of the rubber vulcanised with these agents and that vulcanised with sulphur in the ordinary manner. Should it be possible to obtain results with nitro compounds or peroxides of the same order as those obtainable with sulphur, we have to deal with a discovery not only of scientific interest but possibly of great technical importance and worthy to rank with those of Goodyear and Parkes.

The first attempts to obtain vulcanisation with nitrobenzenes were unsuccessful. I was unable to obtain any indication of vulcanisation using a mixture of plantation crepe with 2 per cent. of dinitrobenzene (Le Caoutchouc et la Gutta-Percha, May 15, 1916, p. 880), and similar experiments by B. D. Porritt (this Journal, 1916, p. 988), using 1-methyl-2,4,6-trinitrobenzene, showed that this substance acts neither as a vulcaniser nor as an accelerator. However, I found later that a very considerable degree of vulcanisation can be obtained under suitable conditions and, having regard to the importance of the subject, I propose to describe in this preliminary paper some of the more important experiments which I have made.

Vulcanisation with nitrobenzenes. The failure to obtain positive results with nitrobenzenes appears to be due, to some extent at least, to the fact that complete translations of the original Russian were not available (*loc. cit.*). Ostromyslenski claims that complete vulcanisation can be obtained with 0.5% of nitrobenzene whereas 6% of sulphur would be required. He also states that metallic oxides, especially litharge, facilitate the process. But in the actual details of his vulcanisation experiments he only quotes two in which rubber was compounded with nitrobenzenes (in these cases 1,3,5-trinitrobenzene) without the addition of litharge or magnesia. In the first of these experiments crepe rubber was compounded with 0.8% of trinitrobenzene and he states that he obtained "complete" vulcanisation. In the second "Permian" with 20% of trinitrobenzene and 12% of linseed oil were heated together but vulcanisation did not take place. It is therefore plain that the evidence brought forward by Ostromyslenski that "vulcanisation" can be obtained with mixes of rubber and nitrobenzenes alone is of a contradictory nature. I have repeated the first experiment using the proportions given but with negative results, nor did the addition of 0.8% of "accelerene" (*p*-nitrosodimethylaniline) help to produce a "vulcanised" product. Having regard to Porritt's failure and my own to obtain vulcanisation under these conditions, Ostromyslenski's claim cannot at present be accepted.

On the other hand I have obtained the effect of vulcanisation with mixes of rubber with di- or trinitrobenzene in the presence of bases such as litharge or magnesia without the least difficulty. In agreement with Ostromyslenski's statements I find that trinitrobenzene is far more efficient than dinitrobenzene. With mononitrobenzene I have not so far been able to obtain a satisfactory result.

The figures given in Table I were obtained with 100 parts pale sheet rubber, 8 parts litharge, and

† It must not be forgotten that the acetone extract of raw rubber usually contains a little nitrogen.

the quantities of *m*-dinitrobenzene and sym.-trinitrobenzene indicated. The specimens were cured in a steam vulcaniser at a temperature of 135°C. for the periods stated.

The original raw rubber gave an acetone extract of 1.8%. Comparing this with the figures for the acetone extracts of the vulcanised rubber, the figures are similar to what would have been obtained with a rubber and sulphur mix—after allowing for the free sulphur simultaneously extracted. That is to say, the acetone soluble constituents of the raw rubber are either somewhat higher or lower than those of the "vulcanised" rubber. The figures for nitrogen indicate that very little of the nitrobenzenes survived the "vulcanisation" or remained in a condition in which they were soluble in acetone. The only exception is the sample containing 4 parts of trinitrobenzene and vulcanised for 5 minutes. Fortunately in the case of the sym.-trinitrobenzene we have a delicate colour reaction by which it may be detected. With a trace of alkali this substance develops a deep red coloration. Examination of the acetone extracts showed an appreciable residue of the trinitrobenzene in (1), a trace in (2), and none in (3) and (4). This test can probably be applied colorimetrically to estimate the "uncombined" sym.-trinitrobenzene, which therefore becomes a very suitable vulcanising agent for quantitative experimental work.

The results of the physical tests show that the products so far obtained possess relatively poor physical qualities. The best results were obtained with the larger proportion of trinitrobenzene, but even in this case the strength as measured by the tensile product is not much more than half that obtainable with a properly vulcanised rubber and sulphur compound.

For comparative purposes, control figures are given in Table 2, (7) and (8), for a mix composed of

mix was also made with 30 parts of magnesia which gave fairly good figures. The results are given in Table 2 and apply to mixes containing 100 parts rubber and the stated proportions of the other ingredients, cured for the stated period at 140°C.

The colour of rubber vulcanised with nitrobenzenes is brown to black (see Table 1). Viewed by transmitted light in a thin stretched sheet, it is yellow-brown and translucent or almost transparent. The dark colour is discharged by treatment with hydrochloric acid after swelling with ether, with the liberation of a trace of hydrogen sulphide, so that there is little doubt but that the colour is due to the formation of a trace of lead sulphide during vulcanisation. This points to the presence of sulphur, possibly arising from traces of sulphur compounds which always hang about a vulcaniser. The amount of lead sulphide would appear to be too small to influence appreciably the reaction with the nitrobenzene or account for the "vulcanised" properties of the vulcanisate. Moreover, litharge can be replaced by magnesia (see Table 2) and probably by other basic oxides with similar results. A comparison of (9) and (10) with (7) and (8) illustrates the effect of trinitrobenzene on an ordinary rubber and sulphur mix.

Vulcanisation with benzoyl peroxide. The discovery of peroxides as vulcanising agents to replace sulphur was announced by Ostromyslenski (J. Russ. Phys. Chem. Soc., 1915, 1453—1461, and 1467—1471). Of the peroxides employed, most of the experiments were made with benzoyl peroxide and I therefore chose this substance for the purpose of controlling the published results. As in the case of the nitrobenzenes, Ostromyslenski's results are of a superficial nature and the vulcanisate is only very roughly characterised by stating whether the vulcanisation was complete and whether the product was dark or transparent.

rubber 100 parts and sulphur 10 parts. With a view to obtaining higher figures some experiments were made with larger proportions of litharge (30 parts) but the results were less satisfactory than with the smaller proportion (8 parts) previously used. A

As is well known, benzoyl peroxide, like other peroxides, is very explosive and consequently cannot be handled in the dry state. For these experiments it was used in the form of a paste with about its own weight of water. In this condition

it presents no difficulty when added to the rubber on the mixing rolls and the small amount of water added is lost by the time the mixing is complete.

In the first series of experiments three mixes were made of the same plantation crepe rubber with the following percentages of benzoyl peroxide (reckoned dry):—A, 0.33%; B, 1.33%; C, 6.67%. Small portions of the sheeted rubber were cured for various periods to ascertain by simple hand tests the cure most likely to suit the particular mixing. With mixings A and B it was found impossible to prepare an even moderately strong rubber, but with mixing C a fairly satisfactory result was obtained. The figures for the tests are given in Table 3.

It will be noted that mixings A and B give very weak rubbers. Nevertheless, the influence of even 0.33% of benzoyl peroxide is clearly marked, as the raw rubber heated alone under the conditions under which these samples were cured would have given a weak, sticky mass whereas the vulcanised samples A, although very weak and adhesive between cut surfaces, were nevertheless superior in physical properties to what would have been produced had the rubber been heated without the benzoyl peroxide. Mix C gave the best results, the vulcanised samples having approximately one-third the strength of a similar rubber vulcanised with sulphur in the heat. Freshly cut surfaces are rather adhesive and the rubber has the feel of being somewhat undercured. Yet on the whole there is a very marked difference between these samples and those containing the smaller proportions of benzoyl peroxide. Samples from mix B occupy an intermediate position. All the vulcanised samples are very pale in colour, quite as pale as the original raw rubber. Those of mix C have indeed a very attractive appearance. They are quite transparent and resemble some of the palest cold cured sheet prepared from plantation crepe rubber.

The samples were acetone extracted a few days after curing and the figures for acetone extract are given in the table. These compare with an acetone extract of 3.0% for the original raw rubber.

The behaviour of the vulcanised specimens to solvents was also noted. In this respect they exhibit a gradual change in properties according to the proportion of benzoyl peroxide in the mix. Thus the vulcanised mix A "dissolves" in a few hours in benzene in a similar manner to a raw crepe rubber. Mix B swells enormously but does not "dissolve." It remains a soft, shapeless, gelatinous lump in the solvent. Vulcanised mix C behaves in the same manner as an ordinary vulcanised rubber, that is to say, it swells considerably but retains its original form. It may therefore be said that the change brought about by heating with benzoyl peroxide is exactly similar to that produced by sulphur and that the products formed have similar properties. The proportion of benzoyl peroxide required to give a fairly complete vulcanising effect is similar to the proportion of sulphur which would be required for the same purpose, but the vulcanisation with benzoyl peroxide is brought about in a much shorter time. Thus, in the above experiments and also in those published by Ostromyslenski, vulcanisation is fairly complete in ten or fifteen minutes at 130°—135°C. with 4–6% of benzoyl peroxide, whereas vulcanisation would have hardly begun with a mix containing 5–6% of sulphur and would require 2–3 hours for completion. On the other hand, attempts I have made to obtain satisfactory vulcanisation with smaller proportions of benzoyl peroxide, but vulcanising for longer periods, have not been successful. Thus it will be seen that with 1.33% of benzoyl peroxide better results were obtained when vulcanising for 30 minutes than for 60 minutes. Further experiments are in progress.

MR. J. H. ROSEASON IN THE CHAIR.

SPONTANEOUS IGNITION TEMPERATURES OF LIQUID FUELS FOR INTERNAL COMBUSTION ENGINES.

BY HAROLD MOORE, M.Sc. TECH.

Determinations of the temperature of spontaneous ignition or ignition point of liquid fuels were first made by Holm in 1913*, and their importance as a test is not yet fully realised.

Flash points and burning points are common tests used for both liquid fuels and lubricating oils. The flash point is the temperature at which an oil will give off sufficient vapour to burn momentarily when a small flame is held close to the surface of the oil. The burning point is the temperature at which vapour is given off by the oil at a sufficient rate to maintain a continuous flame.

These properties provide a measure of the danger from fire which is encountered in the handling and storage of liquid fuels and illuminants. They are of little use as an indication of the behaviour of a fuel in an internal combustion engine. The temperature of spontaneous ignition is the temperature at which a substance surrounded by oxygen or air at the same temperature will burst into flame without the application of any spark or other local high temperature.

Holm made several determinations of spontaneous ignition in a tube furnace whilst Constam and Schläpfer investigated the properties of a large number of fuel oils for Diesel engines in a simple apparatus consisting of a small platinum crucible

* Z. angew. Chem., 1913, 273.

placed in a larger crucible, the intervening space being filled with sand. No means of preheating the incoming air or oxygen was employed, and the experimenters concluded that the error was $\pm 30^\circ\text{C}$.

Some time ago the author required to know the temperature of spontaneous ignition of several fuel oils with which he was experimenting on a Diesel engine, and as no existing apparatus was sufficiently delicate to differentiate between these oils it was determined to make a special instrument for this purpose. The result was the device shown in the accompanying figure.

The instrument consists of a diffusion block of 4 in. diameter mild steel bar $3\frac{1}{2}$ in. deep, the base of which has been turned in order to afford a greater heating surface. The upper end of the bar has been machined so as exactly to fit the platinum crucible used for the estimation of the coking values of oils (dimensions, upper diameter 35 mm., diameter of base 22 mm., height 37 mm.).

A screwed-on cover protects the upper end of the crucible from draughts. This cover is provided with two holes, one for oxygen or air inlet and one for oil inlet. The oxygen or air is preheated to the temperature of the experiment, passing through a thin copper coil situated in a chamber inside the block.

A thermometer and a thermocouple pyrometer are fitted into the diffusion block as close as possible to the base of the platinum crucible and serve to show the temperature of the experiment.

The method of operation when determining values in oxygen is to pass the gas through the apparatus at a speed of three bubbles per second. The quantity of oxygen is observed by means of a wash bottle filled with sulphuric acid, which also serves as drying agent. When the temperature of the block is constant at a desired temperature, one drop of the fuel under examination is allowed to fall through the hole in the centre of the cover of the instrument. If the temperature is much higher than the ignition point a sharp explosion will occur almost immediately, if below the ignition point no explosion takes place. When only slightly above the temperature of ignition, the explosion follows some 10 to 12 seconds after the introduction of the oil.

By repeating the experiment the lowest temperature at which ignition takes place is rapidly determined. This temperature is the temperature of spontaneous ignition. The results obtained by different experimenters using the same instrument agree to within 3°C .

A similar procedure using air instead of oxygen will give the ignition temperatures in air, but in this case the explosion is much less violent and always follows one second after the introduction of the oil.

Spontaneous ignition temperatures are of importance for several purposes, but in this paper I will only deal with the application of this test in the examination of liquid fuels for use in internal combustion engines, in which respect I consider that they are of as much importance as the heat value.

Internal combustion engines, whether operating on 2 or 4 stroke cycles, may be divided into two classes:—

1. Engines which receive the fuel and air before the compression stroke, *e.g.*, petrol and gas engines.

2. Engines which compress the air alone and inject the fuel into the cylinder about the end of compression, that is immediately before inner dead centre, *e.g.*, Diesel engines.

For the first type of engine it is generally desirable to employ high compressions in order to obtain high thermal efficiencies, but the compression allowable is limited by the liability to pre-ignition. Pre-ignition is most liable to occur when the temperature of the mixture due to the heat of

the cylinder walls and the heat of compression approaches the ignition point. Pre-ignition is accompanied by fall of power and loss in efficiency.

In Diesel engines there is no danger of pre-ignition as no fuel is present in the cylinder at the time of compression. No special means are adopted for igniting the charge in Diesel engines, firing being dependent upon the spontaneous ignition of the fuel immediately it enters the cylinder. In Diesel engines it is therefore necessary to employ high compression pressures in order to obtain a sufficiently high compression temperature to ensure the spontaneous ignition of the charge. Provided the temperature is attained it is generally advisable to keep the compression pressure low for mechanical reasons. From these facts it is seen that both for engines which receive fuel and air before the compression stroke and for Diesel engines the temperature at which the fuel will ignite spontaneously is of fundamental importance. In the first case, one is forced to employ a low compression pressure on account of danger of spontaneous ignition, whereas in the case of the Diesel engine this limitation does not appear, but a high compression is required in order to exceed the ignition temperature of the fuel. The temperature attained in the cylinder of an internal combustion engine during compression can be calculated by means of the formula—

$$T_2 = T_1 \left(\frac{P_2}{P_1} \right)^{\frac{n-1}{n}}$$

where T_2 and T_1 are respectively final and initial temperatures absolute, and P_2 and P_1 are final and initial pressures respectively; n is a constant

Press., in atmos.	Temp., abs.	Adiabatic temp. $^{\circ}\text{C}$.	Diesel temp. $^{\circ}\text{C}$.
1	288.0	15.0	38.0
2	352.0	79.1	103.0
3	396.0	123.0	133.0
4	430.0	157.0	162.0
5	459.0	186.0	186.0
6	485.0	212.0	207.0

28	—	—	426.0
32	786.1	513.0	447.0
40	880.5	567.0	487.0

which for air under adiabatic conditions equals 1.408.

On account of the leakage of gas past the piston and the cooling due to the cylinder walls the constant, n , in internal combustion engines approximates to 1.35, the conditions being between those of isothermal and adiabatic compression.

By means of this formula it is possible to calculate approximately the temperature which corresponds to any given compression. The graph of pressure-temperature here shown has been calculated by this means.

It is not at present possible to determine the temperature of spontaneous ignition under actual cylinder conditions, but the relative value can be accurately determined by the device described above. The influence of pressure upon the ignition temperature is a subject for further research.

By an experience of the difference between compressions which have been calculated from the determination of the spontaneous ignition in the instrument, and the experimentally determined point at which spontaneous ignition takes place in an engine, it is possible to build up tables showing the approximate relationship between the experimentally determined ignition point and the maximum compression practicable in a petrol engine. By a similar process it is possible to ascertain the minimum pressures which can be employed in a Diesel engine with any given fuel.

As an example of the influence of the ignition temperature of a liquid fuel we may take the case of alcohol. It has been found in practice that alcohol, though much lower than petrol in calorific power, when run in an engine can be made to yield approximately the same power per unit volume as the latter fuel.

The net calorific power of petrol is about 10,450 calories per gram or 7315 cal. per c.c. The net calorific power of commercial alcohol is about 5420 calories per gram or 4440 cal. per c.c. If both be burnt in an engine with the normal compression (i.e., compression adjusted to suit petrol) the consumptions per B.H.P. hour will be approximately in inverse proportion to the calorific powers of the fuels and over $1\frac{1}{2}$ galls. of alcohol is required to do the same work as one gall. of petrol. Now the spontaneous ignition temperature of petrol (in oxygen) is about 272° C., whilst that of commercial alcohol is 395° C., therefore alcohol will withstand a much higher compression.

The compression pressure of a petrol engine tuned to run on petrol is approximately 90 lb. per sq. in., but with alcohol this pressure may be raised to 200 lb. per sq. in., and by this means the overall thermal efficiency of the engine is raised from about 22% to 35%, when it is found that the volumetric consumption of alcohol per brake horse power hour is approximately the same as that of petrol. Thus though petrol possesses 65% greater calorific power than alcohol per unit volume, the advantages of this high heat value are entirely lost on account of its low ignition point. The ignition temperature is of general interest to chemists as it is a measure of the relative stability of the bodies towards heat. The accompanying table shows the spontaneous ignition temperatures of several fuels which have been determined with this instrument.

From general observations the author has concluded that:—

1. Compounds containing simple molecules have higher ignition points than similar compounds containing more complex molecules. This rule applies to all types of compounds.

2. The ignition points of aromatic compounds are much higher than those of aliphatic compounds.

3. Unsaturated hydrocarbons have lower ignition points than the corresponding saturated hydrocarbons.

4. Ignition points observed in air are higher than those observed in oxygen. This difference for petroleum products is generally 100 to 200 C.

DISCUSSION.

The CHAIRMAN observed that the percentage of hydrogen in the compounds appeared to have some effect upon the lowering of the ignition point.

Mr. J. DRUMMOND PATON said from investigations he had conducted in the United States with regard to gas producers for turbines for marine purposes it was discovered that the determining factor causing rapid ignition and pre-firing was the hydrogen content. It was then endeavoured to ascertain the time constant for ignition of fuel of various hydrogen contents and from the velocity of ignition the actual value was set. It was possible that according to the nature of the compound and the molecular tenacity of the hydrogen the tendency to free liberation would be the determining point, and this determined the linear velocity of ignition.

Mr. L. E. VILES remarked that the spontaneous ignition point of petrol was much lower than that of benzene. Motor car users were aware that even with the same compression better effect could be obtained from benzol than from petrol. He asked whether designers of explosion engines had taken this fact fully into account by producing an engine to run with benzol, which according to the evidence Mr. Moore had brought forward, should be more efficient than an engine indiscriminately used either with benzol or petrol.

Mr. DRUMMOND PATON said the most important heat loss occurred in the period of ignition. Had any investigation been made with a view to isolating the crown of the engine, so that at the actual ignition, the cooling effect and surface of the cylinder would be a minimum? For instance, cast iron was now used. Was it feasible to cover the crown and piston face with isolating material which would diminish heat loss?

Mr. T. O. MORGAN, speaking from the point of view of a motorist, said he had tried various mixtures of petrol and very light petroleum, and had even gone so far as to experiment with mixtures of naphthalene and benzol, without noticing any material difference in the pre-ignition or the overheating of the engine.

Mr. MOORE, in reply, said it was very noticeable that compounds with a high hydrogen content usually had a low spontaneous ignition temperature, but the rule did not apply in several cases, whereas the rules given at the end of the paper could always be applied. Petrol contained more

hydrogen than kerosene, but petrol possessed the higher ignition temperature. Paraffin wax had a still lower hydrogen content, but possessed the lowest ignition point on account of its complexity. Methane had a very high hydrogen content and high ignition temperature. It would be seen that hydrogen content was not a reliable indication of the ignition temperature. It was well known that benzol would stand a much higher compression pressure than petrol. The engine of a racing motor car running at 100 lb. compression would "knock" very badly on petrol. It would work much better on benzol. At the same time it was possible to have pre-ignition with any fuel at comparatively low compressions. There were two causes for pre-ignition. If the temperature of the engine were the same at all parts there would not be pre-ignition until the temperature of compression corresponded with the ignition temperature. If the engine were not perfectly even in temperature, as must always be the case in practice, a plug point or a valve top would get hot and act as a firing agent. This ignition was quite independent of spontaneous ignition, so that an engine might "knock" without the compression being excessively high. The adiabatic curve was calculated from the adiabatic formula, the formula of the other curve (for Diesel engine) being taken from the tangent on the compression curve of the indicator diagram of a Diesel engine. Mixtures with naphthalene had, of course, been largely used. The German army was now running its motor vehicles on mixtures of about 4 volumes of alcohol with one volume of a solution of naphthalene in benzol. The addition of naphthalene cheapened the mixture. The benzol raised the percentage of carbon in the mixture and increased the calorific power. Replying to a further question, Mr. MOORE said that there was a tendency for the spontaneous ignition temperature to vary inversely with the flash point, but these values were better considered as independent.

MR. HENRY PEILE IN THE CHAIR.

UTILIZATION OF WASTE HEAT FROM COKE MAKING.

BY HENRY PEILE.

Up to comparatively recent years very little of the waste heat from coke making was utilized except for the purpose of raising steam for colliery purposes. This was usually done by installing Cornish or Lancashire boilers on the flues carrying the waste heat from the beehive ovens to the chimney. In this way only a small portion of the waste heat was utilized, only one lb. of steam per lb. of coal carbonized.

In 1901 when the patent ovens were erected at Blyth there was added a complete installation of water tube boilers which are fired by the waste heat and gas generated. The steam from 90 ovens is carried direct into an up-to-date power station. The whole of the power generated at this station is delivered into the mains of the Newcastle Electric Supply Company for general distribution in the Newcastle district. In this way the whole of our waste heat and waste gas is utilized to the best advantage as the station is kept running day and night.

At Rowlands Gill there is an installation of 200

beehive ovens. About eight years ago it was decided to utilize the waste heat from these ovens for the production of electricity. Nine Stirling water tube boilers were erected on the main flues which carry the waste heat from the ovens to the chimneys, and where it was found necessary steam driven fans were added to increase the draught on the ovens.

Economizers were also fitted at the back of the boilers so as to avoid any loss of waste heat. As the process of making coke in beehive ovens is more or less intermittent it was decided to erect two Bettington tubular boilers which are fired with a mixture of coal and coke ballast. The fuel is elevated into an overhead bunker from which it falls into a disintegrator where it is ground into a very fine powder. This powder is then blown into the boiler by hot air where it burns with a hot flame, combustion being very complete. Each boiler is capable of producing 15,000 to 20,000 lb. of steam an hour.

In addition to these two boilers a battery of four Stirling boilers was erected, fitted with underfired movable grates specially designed to burn ballast, one of the waste products from coke making. Burning coke ballast is one of the most economical methods of raising steam and at the same time getting rid of waste material from ovens which has otherwise to be disposed of at some cost. This ballast contains about 80% carbon and is therefore a very valuable fuel. From these six boilers it is possible to add to the steam from the coke ovens 60,000 lb. of steam an hour. The whole of the steam from these boilers is super-heated 200° C., and carried direct into the power station.

In the Whinfield Power Station at Rowlands Gill there are installed four Westinghouse turbines fitted with three phase alternators working at a voltage of 6000. All the semachines are interchangeable.

The electricity which is generated at 6900 volts is passed through specially designed transformers, being supplied to the Newcastle Alloy Company at varying voltages suitable for use in their electric furnaces.

As the station is run on a continuous load night and day it is found necessary to keep the transformers cool by means of oil and water. The output of the station approaches thirty million units a year. Special transformers are installed for supplying power to the colliery for pumping, hauling, and lighting purposes.

Electricity is also supplied for lighting purposes in the district.

Ferro-alloys.

The low tension current from the transformers is passed through the walls of the power station into the Alloy Company's works where it is utilised for the manufacture of ferro-alloys and other purposes.

In the early stages of the company experiments for the manufacture of ferro-silicon were carried out in a small electric furnace. On the strength of these experiments larger furnaces were erected until to-day there is a 2000 K.W. furnace producing from 10 to 15 tons of ferro-silicon a day. During the last four or five years the following grades of ferro-silicon have been successfully produced: 25%, 50%, 75%, and also ferro-silicon of exceptional purity, containing 95% of silicon. There is at present under consideration a scheme for the production of one to two thousand tons a year of this material for war purposes.

We have also produced carborundum in our furnaces, but up to now this has not been done on a large scale.

Before the war there was a furnace running on carbide which made one or two thousand tons of

this material, but owing to keen competition it was decided not to continue its manufacture.

The next alloy to be taken in hand was ferro-molybdenum. Considerable difficulty was experienced in making this alloy on account of its very high melting point and the difficulty of getting rid of objectionable impurities. These difficulties have been successfully overcome and an alloy of excellent quality, testing over 80% of molybdenum, is now being produced.

At the beginning of the war it was discovered that practically there were no stocks of ferro-chrome in the country. We were asked to make this alloy and within three or four weeks of war breaking out we were in a position to supply our customers. Since then we have made large quantities of all grades of ferro-chrome with carbon content ranging from $\frac{1}{2}$ % to 10%. The $\frac{1}{2}$ % carbon grade has a very fine crystalline fracture.

Two or three months after war breaking out a large demand for ferro-tungsten set in for the manufacture of high speed steel for munition works. To make this material we erected a specially constructed furnace house fitted with furnaces suitable for the manufacture of this alloy. We are now producing between 300 and 400 tons of ferro-tungsten a year, all of which is being supplied to steel makers in Sheffield. The alloy is sent out in a ground state or in small pieces as required. Considerable difficulty was experienced at first in breaking up this alloy. These difficulties have now been overcome.

Cuprous oxide. Before the war this oxide was all made electrically in Germany. At the present time we are producing between 300 and 400 tons a year.

Our objects in putting up these works were first to utilize the waste heat from our coking plant and second the production in this country of the various ferro-alloys which were all being supplied from abroad. The value of this policy has been fully justified since war broke out, as otherwise great difficulty would have been experienced in obtaining the necessary supplies of alloys to carry on munition work.

I think that perhaps I have said enough to show how a waste product from coke making can be turned to good account either in producing electricity for general purposes or for the production of alloys and for use in other processes in which electricity is employed. If we are to meet competition in the future, we must be prepared to see that there is no waste of any sort going on in our works.

Yorkshire Section.

Meeting held at Queen's Hotel, Leeds, on Monday, January 8th, 1917.

PROF. J. W. COBB IN THE CHAIR.

NOTE ON A DANGEROUS OIL USED IN A WOOLLEN MILL.

BY THOMAS FAIRLEY, F.I.C., AND B. A. BURRELL, F.I.C.

The oil which is the subject of the present note was being used as a wool oil by a firm manufacturing woollen goods. During the process of manufacture, it was observed that white wool when oiled in the usual manner rapidly began to

heat and would no doubt have eventually fired if it had been left unattended to. It was therefore desirable to determine the nature of the oil and its consequent risk of fire.

The oil gave the following numbers:

Free fatty acids (as oleic acid)	87.6
Unsaturation matter	1.0
Cotton seed oil	none
Iodine value	137.0
Yield of insoluble bromides (m.p. above 200° C.)	10.1
Saponification value	193.6
Yield of fatty acids by saponifying, decomposing the soap and drying at 100° C.	98.2
Iodine value of separated acids	137.0
Loss on heating for 1 hour at 340° F.	66.0
Flash point (open test), 268° F.	—
Ignition point, 406° F.	—

The oil therefore consisted of free fatty acids admixed with about 12% of neutral oil. It had a decided fishy smell and its fish origin was further confirmed by the yield of insoluble bromides and their behaviour on heating, as they did not melt at 200° C., at which temperature they began to blacken and decompose, whereas the hexabromides from linseed oil melt to a clear liquid at about 176° C.

The iodine value and the loss experienced on heating showed the oil to be quite unsuitable for use in a woollen mill and this deduction was completely confirmed in actual practice, as the use of this oil nearly involved a serious fire.

We have examined a large number of oils for the Insurance Companies but have not met with a similar oil.

DISCUSSION.

Mr. W. McD. MACKEY was surprised to find so much of the oil volatile at 340° F. He would like to know the composition of the distillate, and whether any water was present. He thought the use of such an oil would make the yarn sticky.

Mr. J. K. S. DIXON said there were large quantities of fatty acids of all kinds on the market at present, among them fish oil fatty acids. The glycerin was required for explosives, and the resulting fatty acids were being used for a variety of purposes, but this was the first time he had heard of fish oil fatty acids being used (except as an adulterant) as a wool oil, for they were undoubtedly dangerous. He was not altogether surprised at the loss on heating at 340° F. In his experience it was almost impossible to obtain a constant weight when drying fatty acids of any kind at a temperature above 140° C.

Mr. B. T. VICKERS did not think the iodine value a reliable criterion as to whether the oil would heat. It only showed the total possible absorption of oxygen and gave no indication of the rapidity with which oxygen was absorbed, which was the real cause of heating. An actual test in a Mackey's tester would be more satisfactory. He thought it possible that this oil might produce "gilding" which was quite different to heating.

Mr. J. F. BARNES said that in his opinion many cases of spontaneous heating were caused by the melting of oil with live steam in the casks; when the resulting oil and water were put on the wool it was more liable to heat than the oil by itself.

Mr. Wm. RUSSELL said that it was a common practice in the United States to use emulsions made of lard oil and water with a little borax. Hence it evidently was not a danger to have water present with oil on the wool-fibre.

Mr. BURRELL replied that the loss on heating was certainly abnormal; it was not due to the presence of water. He regretted that the small quantity of oil placed at their disposal did not permit of an investigation into the nature of the fatty acids present. He did not think, however, that there could be any notable proportion of either linolic or linolenic acids as the insoluble bromides from these acids melted about 175° C., whereas those obtained did not melt at 200° C., and on further raising the temperature began to decompose.

The oil was not distilled but heated in a flat-bottomed basin in an air oven kept at 340° F. This temperature had been selected because it was the minimum flash point allowed by the Insurance Companies for oils used in woollen mills. The loss of weight took place in a non-oxidising atmosphere, viz., the oil's own vapour; when a free current of air was passed through the oven it was not so great, as it was counterbalanced by the gain of oxygen in the residuum, which assumed a hard, varnish-like consistency. Oleic acid was usually regarded as a non-volatile substance and required a temperature of about 182° F. (250° C.) to distil in a current of superheated steam, but when heated in an air bath at 340° F. it lost about one-third of its weight. Some of the cloth oils which contained from 30%—50% of free fatty acids would lose at least a quarter of their weight when heated under similar conditions. He agreed with Mr. Dixon that it was very difficult to attain a constant weight when heating free fatty acids. A good illustration was the washed insoluble fatty acids from butter when dried at as low a temperature as 190° C.

The iodine value was of great use in determining the safety or otherwise of wool oils; it was the measure of the capacity of the oil for absorbing oxygen and therefore of its drying tendencies, and Gellatly had shown the intimate relationship which exists between drying oils and their tendency to spontaneous combustion when exposed to the air in a finely divided state, as when spread on wool. Woollen manufacturers rightly objected to such oils, as not only was there the tendency to spontaneous combustion but they spoiled the yarn by "gumming." With this oil the wool had not merely "gilded" but had actually charred and the mill itself might be regarded as the cloth oil tester.

In this country the use of emulsions or "creams" was still in its infancy, but no doubt the presence of water along with the oil would tend to increase the heating effect. On the other hand their experience of emulsions was that they were generally made from a safe non-drying oil such as olive oil.

NOTES ON THE WORKING OF A DUST FIRED BOILER.

By C. A. KING, M.S.C.

During recent years much discussion has taken place on the necessity for improved utilisation of fuel of every grade, and with this in view it may be of interest to note a recent appliance, which makes use of low-grade raw coal for steam-raising purposes.

It is well known that in ordinary boiler practice the coal lies on the grate in a fairly thick bed with irregular contact with air, so that immediately after firing, the supply of air is insufficient, resulting in incomplete combustion and the production of smoke, and later, when the volatile matter of

the coal has been distilled off, excess of air passes through the flue, both conditions giving rise to considerable loss of useful heat.

On the other hand, with gaseous firing, the combustible matter, in the form of gas, comes into intimate contact with the air supply and is fully burned without the necessity of a large excess of air to ensure complete combustion.

The method of firing the type of boiler to be described can be regarded as being intermediate between these two conditions, the better admixture of fuel and air being secured by grinding the coal to a very fine dust and blowing the required mixture of coal-dust and air together into the combustion chamber of the boiler. It will readily be seen that the particles of coal are brought into much more intimate contact with air than in standard steam boiler practice.

Commercially and scientifically it is important that fine coal, which is a positive source of danger when left in mines, and is unsalable at the present time by reason of its high ash content, and its lying too closely on boiler grates and in gas producers, can be successfully used.

The Bettington boiler (see fig.) is an example of

this type. Small coal is fed from a storage hopper by means of a variable worm gear, into a pulveriser which also acts as a fan, drawing heated air for the combustion of the coal from a

tubular air heater above the boiler. The pulverised coal, carried along by the air current through a separating chamber, across which is stretched a sieve to reject the coarser particles, is burned at the mouth of a water-cooled vertical nozzle. The heated air, in addition to regenerating some heat from the flue gases, to a certain extent dries the coal as it passes through the pulveriser, preventing clogging of the screen.

The dust as used is of such a fineness that 80% of it will pass through a sieve of 200 meshes per linear inch.

The boiler proper consists of concentric vertical rows of tubes terminating at the lower end in an annular metal chamber, and at the upper end in a drum, the combustion chamber being formed by firebricks of semicircular shape lining the innermost ring of tubes.

The flame and hot gases travel vertically up the central axis of the boiler until, nearing the drum, they are turned down and under the firebrick wall, passing again vertically amongst the water, superheater, and air-heater tubes, and finally to the chimney. It should be noted that in the vertical design the action of gravity causes the coal-dust to travel the combustion chamber a second time, whereas in a horizontal or slightly inclined installation the dust tends to fall out of the combustion zone under this influence.

The function of the firebrick lining, apart from acting as a boundary for the fused ash pellicles, is to retain a sufficient quantity of heat to re-ignite the fuel mixture after any temporary stoppage. Its use also prevents short circuiting of the gases around the tubes, and thus gives an increased length of contact for the combustion process to take place. The incandescence surface of the brickwork may also tend in the direction of more complete combustion.

The ash of the fuel in its passage through the furnace of the boiler is converted into a semi-liquid spray, which coalesces on the lining, slowly trickles down, and drips from the bottom edge into the ashpit, from which it is raked out at intervals. It is of obvious advantage to use a coal the ash of which has a low fusion point, or to modify a refractory ash by suitable addition to the coal. Many analyses show that this clinker contains no combustible matter, and theoretically this is excellent, but with furnaces of this type it is usual to find in practice that a certain proportion of the coal is not completely burnt to ash but passes out of the boiler as a coked dust containing up to 10% of fixed carbon and sometimes up to 5% of volatile matter. This is undoubtedly only a question of design, but at the present time a dust catcher may sometimes be usefully installed.

The ultimate test of the efficiency of a boiler, however, is its evaporative power. It has long been the custom to compare boilers upon the basis of the number of pounds of water evaporated by each, per pound of fuel, but this is likely to be deceptive, especially if, as seems probable, coals of much inferior quality are brought into use. The true efficiency of a boiler is represented by the number of heat units which are utilised in heating the water and converting it into steam compared with the total number of heat units supplied in the fuel used. In the results of the tests below both methods of expression are given.

On one day two tests were made. No interruption of the ordinary working condition was made except that the coal was weighed and the water measured. Temperatures and pressures at various points were also taken throughout the test. The boiler was run at about normal load for 5½ hours

common with all high temperature boilers, soft water should be used to avoid scaling and consequent overheating of the tubes. Full steam pressure (160 lb.) can be raised within thirty minutes from lighting off, and the manipulation is very simple, the firer only having to alter the mechanical regulation of the coal and water feeds according to the variation in load.

No inconvenience from floating coal dust has been observed, the boiler house being clean and tidy.

Acknowledgment is made to The Directors of the Farnley Iron Co. for permission to include the results of the tests, and to Messrs Fraser and Chalmers, Ltd., for the use of the diagram.

ADDENDUM.

The method of obtaining the balance sheet of heat in the various parts of the boiler depends on temperatures and analyses of the flue-gases being taken at the same time at various points. The relationship of these to a conventional temperature of combustion worked out by Bunte, gives the loss of heat in the flue-gas at that particular point as a percentage of the total heat of combustion of the fuel. Correlated with figures obtained from the total heat in the steam raised, all in terms of the percentage of heat in the fuel, a simple calculation then separates the heat retained in the various parts of the boiler.

Thus in the present example on normal load :

	Heat lost from.	Heat retained by.
	%	%
(A) Super-heater (calc. from super-heated steam tables)	—	6.8
(B) Boiler, super-heater, radiation (entering air heater)	18.6	81.4
(C) Boiler, super-heater, radiation, air heater (leaving air heater) ..	16.8	83.2
(D) Boiler, super-heater, air heater, (heat in steam)	—	76.0

Therefore :—

Loss by radiation = C—D	= 6.3
Retained by air heater = C—B	= 1.8
Retained by super-heater = A	= 6.8
Retained by boiler = B—(6.3+6.8)	= 68.3
Loss in flue gas = (100—C)	= 16.8

100.0

DISCUSSION.

The CHAIRMAN called attention to the economic importance attaching to the utilisation of small coal, and to the practical difficulties which were encountered in dealing with dust in boilers, gas-producers, and coke-ovens respectively.

Mr. Moss asked what was the horse-power of the pulveriser?

Mr. B. G. McLELLAN said that he had made some tests on a Bettington boiler a few years ago. With good coal it had been frequently observed that the cost of preparing coal, drying, grinding, etc., more than counterbalanced the increase of efficiency obtained. With low-grade coal, which was the rational fuel for this type of firing, there might be a greater margin, but then there was a tendency for the flame to go out, and for the combustion to be incomplete, as was shown by the clinker being accompanied by particles of coke.

For this type of boiler where the flame temperature was intense, the use of a soft water was imperative. In absence of a natural supply, this meant an efficient water softener under regular chemical supervision. As evaporation proceeded, concentration of salts took place in any boiler using softened water. In Lancashire boilers and water-

tube boilers, with tubes arranged to provide circulation of the water, this might be kept under control, but where there was no definite circulation of water, intense local concentration might occur with crystallisation of salts and as a result, burning or explosion of tubes.

The fact that there was not a definite course of circulation, constituted a distinct weakness in this boiler.

It would be interesting to know the author's experience on the life of the firebrick lining, also if any attempt had been made to employ a lining of the same type as the ash of the coal in use, *i.e.*, an acidic brick for coal with an acidic ash, and *vice versa*.

Mr. WILLIAM McD. MACKEY asked if the boiler was intended for a poor coal, *i.e.*, a coal high in ash, or was it intended that good coal should be ground. In the case of a poor coal he considered that it was better to wash it and then use it in the ordinary way as a boiler fuel, or grind and coke it. In pit practice about half the coal was sold at above cost price, and the rest, the small coal, below, and it was this that was wanted for coke making and ordinary boiler fuel; but the smallest, the fine slack and smudge, contained the bulk of the dirt or ash. The dirt came from the partings in the seam, from the roof, and from the floor, and could be readily washed out of the small coal, except in the rare cases in which the dirt was intergrown with the coal. He agreed with Mr. McLellan's remarks with reference to the action of the fine ash on the brickwork of the furnace.

Mr. C. P. FINN asked for a description of the disintegrator and also what amount of moisture caused this to clog. In coal washeries the fine dust washed away from the coal was allowed to settle out from the water; he wondered whether this would be of any use with these boilers.

Mr. F. MILLER said he understood that it was impossible to store coal dust owing to risk of spontaneous heating. In the present instance, however, the coal was ground immediately before use. He also had seen it stated that it was impossible to screen the coal if it contained more than 1% of moisture. What was the life of the firebrick lining?

Mr. DOUGILL asked if the boiler was adapted to fine coke breeze?

The AUTHOR replied that it was intended to show an improved method of steam-raising by using low-grade small fuel, though with good coal an increased efficiency over ordinary practice would be obtained. Fine coal, which was otherwise wasted, either in the mine itself or on washing plants, could be used if sufficiently dry. Coal containing up to 11% of moisture had been successfully burned though necessitating a rather larger excess of air to prevent clogging in the pulveriser. It was pointed out that air at 60° C could carry 19% of its volume of water vapour, much more than was contained in the coal, and the dust passing to the screen was found by direct determination to be perfectly dry. Coke breeze would have to be much more finely pulverised than coal to be satisfactorily used.

The pulveriser was of the "rotary" type, the blades lasting about three months. During the first test the power consumed by it was 29 EHP, which would correspond with approximately 3% of the steam raised, assuming 15 lb. of steam per kilowatt. No tendency for the flame to go out had been noticed during a period of two years' working.

Definite circulation of water in this boiler was doubtful, and the necessity for the use of soft water had been noted. The life of the brick lining was not a simple question of the acidity or basicity of the ash as compared with the firebrick, though that was important, the physical structure and previous treatment of the clay being also a prime factor.

Communications.

NOTE ON GHEE.

BY R. C. BROWNING, M.A., AND M. PARTHASARATHY
(Government Analyst's Laboratory, Colombo,
Ceylon).

In two papers (Analyst, 1910, p. 313, and 1911, p. 392) Bolton and Revis give figures for the Reichert-Meissl value of ghee. They state that it is usually approaching or even exceeding 30.

Kesava Menon (J. Soc. Chem. Ind., 1910, 1128) finds a Reichert-Meissl value of 25.7 for cow ghee and 18.21 for buffalo ghee. These samples were made at the author's home and were thus genuine.

K. H. Vakil (J. Soc. Chem. Ind., 1915, 320) finds that the Reichert-Meissl values vary from 20 to 25.

The writers of this note have frequently had samples of ghee which appeared to be genuine (from the analytical figures) but which had Reichert-Meissl numbers lower than those of Bolton and Revis.

They have therefore prepared samples of ghee in the laboratory, from cows and buffaloes milked under their personal supervision.

The following is a typical example:

Sample.	Origin.	Butyro- refracto- meter reading at 40° C.	Oleo- refracto- meter at 45° C.	m.p.	Acid value.	Reichert- Meissl value.
1	Buffalo	44°	-28°	43°	0.83	18.9
2	Cow	45.4°	-29°	38°	0.48	22.3

The Reichert-Meissl numbers of four buffalo ghees prepared in the laboratory were 18.9, 18.86, 27.0, and 30.2.

Reichert-Meissl numbers of cow ghees also prepared in the laboratory were 21.4, 22.3, 23.9, 20.9, and 20.9.

Ghees prepared from imported frozen Australian butter had Reichert-Meissl values 29.4 and 28.0 respectively.

It will thus be seen that it is quite possible for genuine ghees to have Reichert-Meissl values well below 30.

The writers' experience is that the oleo-refractometer is most valuable in the preliminary examinations of ghees.

ORGANIC VULCANISING ACCELERATORS.

BY D. SPENCE.

In view of the world-wide publicity given in recent times to the above subject it would seem to be no longer amiss, but, indeed, desirable to put on record a few facts in refutation of some of the very erroneous statements which have appeared in the literature of this subject. The various writers reviewing this subject, and in particular Dittmar,¹ Gottlob,² King,³ Penchey,⁴ have all, without exception, assumed that that which is not proclaimed from the house top is not known, and from these faulty premises have drawn certain equally erroneous yet sweeping conclusions which it has been my intention sooner or later to nullify and correct. I shall take the various references in the order in which they appear.

Dittmar¹ in that part of his article which deals with the subject of organic accelerators refers to the first patent application² on this subject as follows:—"The 16th of November, 1912, marks an important turning-point in the development of the rubber industry. For on the publication of this patent there began a systematic hunt in German, Russian,

Austrian, and in American rubber factories for organic vulcanising accelerators. The ice was broken: the practical value was recognised." This patent deals with the vulcanisation of natural or of synthetic rubber using piperidine or its homologues as accelerators.

In similar, if somewhat more modest, language Gottlob² describes the discoveries of the Elberfeld Farbenfabrik, and in all the subsequent patents dealing with the subject of the vulcanisation of natural or of synthetic rubber by this company the novelty as well as the scope of their discoveries are described in no uncertain terms.

In the article by King³ dealing with this subject it is stated that the use of organic accelerators dates from the discovery of synthetic rubber. "This product cannot be vulcanised without the addition of some of the organic catalysts." . . . "The first patent granted for an organic accelerator was to Bayer & Co. (German Patent 265,221, November 16th, 1912) for the use of piperidine."

According to all these authorities then the discovery of the principle of vulcanisation whether of natural or of synthetic rubber by means of organic catalysts dates from the disclosures of the Elberfeld Farbenfabrik in November, 1912. And by reason of the sources of the information I am inclined to believe that this is true so far as Europe in general and Germany in particular are concerned. But as one who has studied this aspect of vulcanisation, continuously, for the past several years, both scientifically and industrially, I must take exception to their generalisations as far as America is concerned. The "systematic hunt" which Dr. Dittmar refers to, took place in America not after but several years previous to the first disclosure in German patent literature to which he refers, and I hope to demonstrate that this field had been covered and the scope of the discovery determined long before the Elberfeld Farbenfabrik had even commenced to investigate this subject. All their claims as well as those of others to novelty in this connection can readily be disposed of, coming as they do at this late date.

Substantial proof of my assertion is indeed to be had from a careful analysis of my own previously published work on the subject of vulcanisation. In the *Kolloid Zeitschrift*⁶ of 1912, more than six months before the Elberfeld Farbenfabrik made application for their first patent on this subject I described certain experiments the significance of which passed apparently unobserved even by the chemists of the Elberfeld Farbenfabrik. In this communication I wrote as follows:—"More than a year ago we prepared samples of two carefully-chosen mixings. Both mixings were made from partially purified rubber with about 9% of sulphur. In order to make the investigation as comprehensive and complete as possible the two mixings were purposely chosen so that two quite distinct types of compound as different as possible in their properties were obtained. The first was a slow-curing compound deteriorating rapidly; the second, on the other hand, was a quick-curing mixing which we knew from experience would resist deterioration indefinitely. . . . Two compounds of the same general character as No. 2 were prepared; both these compounds contained about 9% of sulphur and were free from mineral compounds."

A moment's consideration of the statements italicised by any chemist of india-rubber familiar with his subject should at once make evident the fact that the acceleration of vulcanisation in the two compounds described must have been produced by novel methods, by substances organic in nature, for the use of litharge, magnesia, or of any of the accelerators then known is expressly precluded. As a matter of fact the first of these two compounds actually contained 1% of piperidine, the very substance referred to in the German patent of November 16th, 1912; the

formula for the mixing was as follows:—Plantation Para 100 pts., sulphur 10 pts., piperidine 1 pt. Without the use of piperidine in this mixing the results given in Table V. of the communication referred to would have been utterly impossible, as I knew full well before I made the test, while debating in my mind as to the best type of compound and accelerator to use for these experiments on vulcanisation at low temperatures.

Now in regard to the discovery of vulcanisation of synthetic rubber by means of organic accelerators, also accredited to the Elberfeld Farbenfabrik. The vulcanisation of these products by this means was actually carried out and successfully accomplished by me both for isoprene-caoutchouc and for the dimethylcaoutchouc from pinacone at a time when the large industrial concerns in Germany engaged in the study of the synthesis of india-rubber were in the dark as to their lack of success in the vulcanisation of their products. The proof of this assertion and the complete vindication of my position with reference to the subject in general I am content to leave over until a later date. At that time I will also bring evidence to show that even the reagents claimed by Peachey (English Patent 4263 of 1914) were known to me and had been used by me both scientifically and industrially several years before his application was applied for.

In conclusion, although it cannot be denied that Germany has taken the lead in many of the discoveries of science in its application to industry and in the present instance has again sought to establish her priority in invention, I believe that I have already brought out enough evidence to refute her claims in this instance and to show that, notwithstanding her silence, America has not been asleep but on the contrary took the lead in the discovery of this one fundamental principle of vulcanisation which has only now become universally recognised.

Industrial Notes.

COMMITTEE ON GLASS AND OPTICAL INSTRUMENTS.

The Advisory Council of the Government's Department of Scientific and Industrial Research have added to the list of their technical Committees a Standing Committee on Glass and Optical Instruments. The membership of the Committee is as present as follows:—Professor H. Jackson (Chairman), Mr. Conrad Beck, Professor C. V. Boys, F.R.S., Mr. F. J. Cheshire, Mr. A. E. Conrady, Mr. A. S. Esslemont, Mr. J. W. French, Dr. R. T. Glazebrook, F.R.S., Sir Howard Grubb, F.R.S., Mr. E. B. Knobel, Dr. T. R. Merton, Professor J. W. Nicholson, Captain Cragh Osborne, R.N., Mr. H. J. Stohart, Mr. J. Stuart, Mr. M. P. Swift, Mr. William Taylor, Mr. F. Twyman, Lt.-Col. A. C. Williams, Mr. W. F. J. Wood.

The Committee met on December 11th, and, having regard to the urgency of the problems requiring investigation in respect of these essential industries, appointed a series of Sub-Committees to which various special problems were referred. Among these problems the more important are:—

- (A) Raw materials for glass and glass making.
- (B) Optical properties of a large range of glasses.
- (C) General physical and chemical properties of glass and glassware for scientific and industrial purposes.

- (D) Testing and standardising of glassware.
- (E) Workshop technique.
- (F) X-ray glass apparatus.
- (G) Optical calculations and lens designing.
- (H) Optical instruments.
- (J) Translation of foreign works on optics.

This brief description indicates certain lines of investigation which have been brought forward. The Standing Committee does not propose to limit itself to these subjects, but is prepared to consider and report upon the necessity for investigation in other directions, relevant to its terms of reference. Manufacturers who have experienced difficulties requiring investigations for their solution in connection with the subjects of glass and optical instruments or who desire to make suggestions for special researches on these subjects are invited to communicate in the first instance with the Secretary of the Research Department, Great George Street, Westminster, S.W., who will direct the correspondence into the appropriate channels for attention.

ELECTROMETALLURGY IN THE UNITED STATES IN 1916.

According to an article in the Jan. 1st issue of *Metallurgical and Chemical Engineering*, there was a greater commercial development of electrometallurgical industries in the United States during 1916 than at any time during recent years. The heavy consumption of alloy steels formerly made largely in the crucible, the increased demand for ferro-alloys caused by the greater production of alloy steels, the shutting-off of imports of ferro-alloys and other electrometallurgical products, like aluminium and magnesium, the high prices of metals permitting experimentation with new processes—all these are contributory causes of the recent industrial advance in electrometallurgy.

The installations of electric steel furnaces in America were approximately doubled in 1915, and the progress continued at almost undiminished rate in 1916. The chief trouble met with is a lack of experienced workers. High-speed tool steel is now being manufactured in 6-ton heats as a regular procedure, in contrast with the 100-lb. pour of the crucible. The heavy demand for high-speed tool steel and the difficulty of securing crucibles at any price has made the electric steel furnace an economic necessity.

A considerable number of electric furnaces have been installed in foundries for the manufacture of steel castings. More installations are contemplated involving the use of the electric furnace in a duplex process with the open-hearth or the converter. Several electric furnaces are melting ferromanganese before addition to steel.

In Germany—formerly the largest producers of electric-furnace steel—the heavy demand for tool steel has also resulted in an increased use of the electric furnace for steel making. In August the production reached 17,000 tons per month, or six times the monthly production at the outbreak of the war. On the other hand, the production of crucible steel in Germany has remained stationary, there being no new installations of any size. The monthly production of electric-furnace steel in Germany is now double the crucible output.

On a smaller scale there has been a heavy increase of ferro-alloy manufacture in the United States. Three new manufacturers of ferrosilicon started production during the year. At the outbreak of the war about half of the domestic ferrosilicon consumption was imported, but now practically all ferrosilicon needed for consumption is manufactured in the country, and a small amount is being exported. To provide part of the needed furnace capacity a calcium carbide plant in

Niagara was converted to ferrosilicon manufacture. During the period in question the domestic consumption of ferrosilicon has doubled and is now estimated at 45,000 tons annually.

The largest domestic producer of ferrochrome was able to supply the increased needs of the steel industry, but it is probable that if this producer had not held large stocks of foreign ore, there would have been a shortage of ferrochrome. The development of California mines has been slow and the average grade of the chromite was too low for alloy manufacture. With other alloys, such as ferrotungsten, ferrovanadium, ferrotitanium, and ferromolybdenum, there has been an increase of production and several plants have been established. There is now sufficient plant capacity in the country for filling all domestic requirements of ferrotungsten, and for the first time considerable quantities of the alloy are being exported. Exports of ferrovanadium have doubled since 1915. Most of the new producers are using the electric furnace. Ferrotitanium is produced at Niagara to the limits of plant capacity. A fair quantity of ferromolybdenum is being manufactured in the United States, and towards the end of the year there was a marked increase in demand for foreign shipment, which is believed to have to do with the lining of big guns. Ferro-uranium was produced commercially for the first time in the States, and may be added to the new products of the electric furnace.

Aluminium manufacture in the United States enjoyed in the past year maximum production and maximum prosperity in its history, the lead over European producers being increased. The North Carolina plant of the Southern Aluminium Company, which in 1915 passed into the hands of the Aluminium Company of America, is expected to start operation in the near future. Further large projects for increased plant capacity are under way. The imports dropped to about one-tenth of the normal quantity and exports doubled. There are no new producers besides the Aluminium Company of America, up to the present. J. W. Richards estimates that by 1925 aluminium will be third in importance among metals (measured by weight), and will be outranked only by copper and iron.

As a result of operations started in 1915 several plants are producing very pure metallic magnesium on a small but commercial scale by electrolysis.

Among new electrometallurgical enterprises electrolytic zinc looms large. There is the plant of the Anaconda Copper Company at Great Falls, Montana, with a production of 100 tons of electrolytic zinc per day, while as a result of the Bully Hill experiments of the General Electric Company a \$350,000 electrolytic zinc plant is being erected at the Mammoth smelter in California. As in 1915, there was in 1916 practically no development of electric-furnace smelting of zinc ore. It would seem that electrolytic zinc has the upper hand, and may be able to keep it, although in a measure its sudden development to a commercial process has probably been accelerated by the facilities of the Anaconda company available for placing an experimental development on a commercial basis.

The electrolytic copper refineries that were hit so hard at the start of the war have all been working to the limit of their capacity. Electrolytic refining has also been successful with tin; it has often been stated that Bolivian tin ores would always be out of question as the tin produced would be too impure; the success of the combined tin smelting and electrolytic refining plant of the American Smelting and Refining Company at Perth Amboy has proved that the additional refining cost is by no means prohibitive, and the only reason why enlargements have not yet been made is the present high cost of building materials.

HIGH VACUUM PUMPS.

In a recent issue of the *Journal of the Franklin Institute*, Dr. Irving Langmuir, of the General Electric Company, Schenectady, describes a new form of vacuum pump, which is characterised

Glass condensation pump.

by extreme speed and the high degree of vacuum attainable. In these pumps the gas is carried into a condenser by means of a blast of mercury vapour, the action being similar to that in a steam ejector and in a Gaede diffusion pump. The method by which the gas is brought into the mercury vapour blast in the new pump is based on a principle which differs essentially from that employed in the steam ejector or Gaede pump. In the new pumps, which are called "condensation pumps," the gas to be exhausted is caught by the blast of vapour and is forced by gas friction to travel along a cooled surface. By maintaining this surface at such a low temperature that the condensed mercury does not re-evaporate at an appreciable rate, it is possible to keep the mercury vapour from escaping into the vessel which is being exhausted. The action of the pump therefore depends primarily on the fact that all the atoms of mercury striking a mercury-covered surface are condensed, no reflection from the surface-taking place. The pumps can be worked at a very high speed (3000—4000 r.c. per second, or even more), and there is no lower limit, other than zero, to which the pressure may be reduced. By means of this pump, pressures lower than 10^{-6} bars have been produced and measured.

One form of the condensation pump, made entirely of glass, is illustrated here. Mercury vapour from the flask, A, is carried through the thermally insulated tube, B, to the nozzle, L. The vessel to be exhausted is connected to R. The gas from this vessel passes through the trap, G, and tube, F, into the annular space, E. At P this gas comes into contact with the mercury vapour blast issuing from L, and is thus forced outwards and downwards against the walls of the tube, C, and is finally driven down into the space, D, from which it escapes into the rough pump connection, N. The mercury which condenses on the sides of the tube, C, passes back through M into the boiler, A. This construction prevents the condensed mercury passing into the annular space, E, and thus the trouble arising from a mercury blast into the tube, F, is avoided. It is

essential that the end of the nozzle, L, should be below the level of the water in the condenser, J. The distance between L and D must be sufficiently great that no perceptible quantity of gas can diffuse back against the blast of mercury vapour, and so that a sufficiently large condensing area is furnished. The other dimensions of the pump are relatively unimportant. The pumps may be made of any size. The larger the pump the greater will be the speed of exhaustion. Such pumps have been constructed with the tube, B, and nozzle, L, in sizes varying from $\frac{1}{4}$ inch to $1\frac{1}{2}$ inch.

In working the pump, the mercury boiler, A, is heated either by gas or electrically so that the mercury evaporates at a moderate rate. A thermometer in contact with tube, B, under the heat insulation, usually indicates a temperature between 100° and 120° C. when the pump is working satisfactorily. Under these conditions the mercury evaporates quietly, and no bubbles are formed, so that there is no tendency to bumping. With an electrically heated pump in which the nozzle, L, was $\frac{3}{4}$ inch diameter, the pump began to work satisfactorily when the heating unit delivered 220 watts, but the speed of exhaustion remained practically unchanged even when the heating current was increased to about 550 watts.

The back pressure against which the pump will operate depends, however, on the amount and velocity of the mercury vapour escaping from the nozzle. Thus with 220 watts the pump mentioned would not operate with a back pressure exceeding 50 bars (bar = 0.0075 mm. mercury pressure), whereas with 500 watts back pressures as high as 800 bars did not affect the working.

The condensation pump, like any other mercury pump, does not remove mercury vapour from the system to be exhausted. (The vapour pressure of mercury at room temperature is about 2 bars.) By the use of a trap such as that shown at G, this vapour pressure may be lowered, and mercury vapour can be entirely eliminated by the use of solid carbon dioxide or liquid air.

The condensation pump also lends itself to construction in metal, and two types of metal pumps are illustrated in the article referred to (J. Franklin Inst., 1916, 182, 719—743).

PLANT DEPRECIATION.

In a paper before the Institution of Electrical Engineers, Messrs. F. Gill and W. W. Cook discussed the principles underlying the computation of depreciation of plant. Neither the engineer, nor the financier, nor the accountant is competent to settle the question in any particular case, because to obtain correct results there must be co-operation among the three. The function of the engineer is to provide the information necessary regarding the plant, such as first cost, residual value, and life. The financier has to furnish information regarding the money, the amount available, the rate at which it can be borrowed, and the rate that can be obtained for the loan of it. The accountant has to provide accurate records based on the decisions arrived at, and to see that the real results are neither disguised nor hidden.

Considering that this common method can best be studied in the annual charges for plant, determined in advance of construction, these are analysed these into four principal parts:—(1) Return on capital outlay, treated as a charge, because no engineer is justified, except in special circumstances, in putting down plant that will not pay a return on its own capital; (2) depreciation, including "renewals" or provision for diminution in value of plant in place and working by reason of causes outside the owner's control, such as age,

wear, and accidents, and "improvements" to enable the owner to take plant out of commission before its physical life is exhausted in cases where, either from progress of the art or growth of the business, it is economically advisable to do so; (3) maintenance, or the cost of keeping plant in as good condition as is advisable, but not of renewing it; and (4) operation, the cost of working the plant. To determine the amount in the annual charges for depreciation it is thus necessary to estimate the first cost, residual values, and the physical and economic lives of the different classes of plant. The treatment of the capital account must also be fixed and the charge for return on capital estimated.

The reserves are preferably handled by means of two funds, for "renewals" and for "improvements." The calculation of the amounts to be contributed to these two funds must include the interest which should be earned by the money before it is required at the end of the life. The amount which should be in the renewals fund gives the correct diminution in value, when considering the value to the owner, of the plant in place and working, at any period in its history. The amounts annually put to the two funds, renewals and improvements, determine the correct charge against the undertaking for the purpose of assessing profits, fixing rates, and, under certain conditions, assessing the value of the undertaking as a going concern.

There are several methods of treating the provision for depreciation, but substantially they reduce to the following:—(1) Maintenance method, in which no regular sum is put aside, the plant being maintained and renewed out of revenue expenditure; (2) reducing balance method, in which a uniform percentage is deducted each year off the reduced capital cost; (3) straight line method, in which the annual charge is the ratio of one year to the total time or life; and (4) sinking fund and annuity method, in which value is given to the interest the fund will earn until it is wanted.

The first method affords no means of calculation, is bound to be irregular, and since no charge can be made until a renewal actually takes place, is always in arrear unless and until a complete renewal is effected. The second is very frequently employed to ascertain the amount to be allocated for depreciation at the end of a year, but it results in a relatively heavy charge in the early years and a very light one in the last years.

The third method, as generally used, is very simple. Assuming the first cost to be £100, the residual value £13, and the economic life 19 years, then £87 has to be found in that period, and therefore all that is required is £4.58 per annum for depreciation, the total charge, with £5 for return, being £9.58 per annum. But the present value of 19 annual payments of £9.58 at 5% is £115.77, instead of £94.86, and the method does not pass the test of total cost. If £4.58 be set aside annually, £87 will be accumulated at the end of 19 years, but since it is not prudent to leave money idle, interest ought to be and will be earned by the money set aside. If interest at 5% is added to the growing fund, there will be at the end of the 19 years not the £87 required, but £138.84; hence the yearly payments must be reduced below £4.58 until the amount is just sufficient to accumulate only the £87 required. This needs an annual payment of £2.85 for the 19 years.

If the earned interest be not added to the fund, but credited to the general revenue account, as is generally the practice of those who uphold the straight-line method, the effect is to increase the revenue, with the result that a higher return on capital is obtained, the interest earned by the depreciation fund not being required for the plant. This is a violation of the hypothesis that a stated return on capital is to be earned, no more and no less, and the present value of all the

payments exacted for the plant is too great, being £115-77.

If instead of accumulating a fund the capital is partly repaid each year, the present value is correct at £94-86, but the annual charges vary each year, and there is no condition as regards the plant which requires a varying annual charge.

In the annuity method a part of the capital is repaid each year and a return is paid on the capital outstanding, while in the sinking fund method the capital remains fixed at £100 and a fund is built up gradually against the end of life, at which time, and not till then, the money will be required either to repay the capital or to replace the plant. In both methods the total charge is uniform at £7-85 per annum, made up in the former case of the decreasing return component and an increasing depreciation component, and in the latter of uniform charges each year both for return and for depreciation. In both methods the present value of the series of components is £94-86. Thus they are both correct in amount, satisfy all real requirements demanded by the plant, and being uniform can be readily handled. In practice it is not usual to repay the capital fractionally each year; the money set aside for depreciation is generally accumulated until it is wanted, and the sinking fund method satisfies all requirements so far.

ELECTROLYTIC HYDROGEN AND OXYGEN.

In a recent issue of the *Engineering and Mining Journal* L. V. Curran gives an account of the operation of an electrolytic hydrogen and oxygen plant at the Copperhill property of the Tennessee Copper Co.

The principal equipment is as follows: One 25-kw. 60-volt direct current generator, direct-connected to one 30-h.p. 220-volt 60-cycle three-phase 900 r.p.m. slip-ring-motor; fifteen oxygen-hydrogen generating cells; two 59-cu. ft. capacity gasometers; two $6\frac{1}{2} \times 3 \times 5$ -in. two-stage tandem belt-driven compressors, 200 r.p.m.; one 15-h.p. 220-volt 60-cycle three-phase 1150 r.p.m. induction motor; ten 15×48 -in. drums, tested to 1000 lb. water pressure, fitted with right-hand connections; fifty-four 15×48 -in. drums, tested to 1000 lb. water pressure, fitted with left-hand connections; two 4×10 -ft. receivers tested to 300 lb. water

pressure. The plan of the plant is shown in the accompanying figure.

The cells consist of an iron tank $10 \times 6 \times 47$ in. high, forming the positive electrode, and two $\frac{1}{8}$ in. iron plates, $36 \times 39\frac{1}{2}$ in. high, forming the negative electrode, an asbestos fabric entirely inclosing the latter and preventing the gases from mixing. The cells are spaced on 9-in. centres and enclosed in a cellroom $18 \times 9 \times 8\frac{1}{2}$ ft. high. The water is kept charged with sufficient caustic soda to maintain a density of 26° B., about 75 lb. per cell being required at first filling.

The most economical rate of generation with these cells is reached when the current is 400 amp.; so the current is kept at that strength, 40 volts being required when cold and 36 volts at the running temperature, which is about 127° F. (51° C.). In order to minimise the danger of the gases getting mixed, the equipment for collecting the gases from the cell tops and for compressing into the drums and receivers is arranged entirely in duplicate, with no cross-connections, the scheme of left-hand and right-hand connections being carried out on the compressor discharges and drum connections, for hydrogen and oxygen respectively. Further precautions are taken by watching the polarity of the generator and by making frequent tests of the oxygen.

The gases are collected into $\frac{1}{2}$ -in. manifolds with rubber-hose connections to each cell, and are led into two gasometers which, as often as filled, are pumped down by the two compressors driven by the 15-h.p. motor through a lineshaft. The oxygen is pumped into drums and used for welding and cutting and for certain heavy lead work.

The hydrogen is pumped into the "hydrogen system," consisting of two 4×10 -ft. receivers, one at the gas plant and one at No. 1 sulphuric acid plant, approximately 800 ft. distant, the two receivers being connected by a $\frac{1}{2}$ -in. line. From the acid-plant receiver the gas is piped through the plant in $\frac{1}{2}$ -in. and $\frac{3}{4}$ -in. lines, being used at 4 lb. pressure. The pressure carried on the gas-plant receiver is 200 lb. and on the acid-plant receiver, 50 lb. Hydrogen is also compressed in drums for use on work at the other plants or in places isolated from the hydrogen system. Compressed air is used with the hydrogen for lead work except where there are no air lines or where the work is particularly heavy, when the oxygen is used. Hydrogen is also used with oxygen at the welding shop in cutting.

The output of the plant was found to be 12½ lb. of hydrogen and 97½ lb. of oxygen per 24 hr. The present hydrogen consumption is 14½ lb., 5½ days per week. It is therefore necessary to operate the plant 15½ hr. per week, or 91.4% of the time. The present demand for oxygen is 19½ lb. per day, six days per week. Current is bought at \$30 per h.p.-yr.; the power input of the plant is 26-25 h.p.

The first cost of the plant was \$6287.42. The present operating costs are:—

Yearly operating costs.

	\$
Power, 26-25 \times \$20 \times 91.4%	719.78
Engineers, 8007 hr. at 185c.	1487.68
Interest and depreciation, 12%	754.49
Inspector lines, 4536 hr. at 165c.	759.18
Total yearly expense	\$3721.43

At the present rate 6022.5 lb. of oxygen and 4086.9 lb. of hydrogen are used per year. The cost of replacing the service with bought oxygen and hydrogen generated with zinc and acid would be about \$17,000.

Journal and Patent Literature.

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—

English.—*Gd.* each, to the Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C.

United States.—*Is.* each, to the Secretary of the Society, who has to furnish the U.S. Patent Office with the following data:—

Patent number, date, name of patentee, and title of invention.

French.—*1 fr.* 05 c. each, as follows: Patents dated 1902 to 1907 inclusive, Belin et Cie., 56, Rue Ferou 8. Paris (3e.)

Patents from 1908 to date, L'Imprimerie Nationale, 87, Rue Vieille du Temple, Paris.

I.—GENERAL; PLANT; MACHINERY.

PATENTS.

Steam and similar bodies: Device for freeing — from impurities. C. Hülsmeier, Düsseldorf-Grafenberg, Germany. Eng. Pat. 8134, Mar. 31, 1914.

THE steam is passed in an upward direction through several separate spiral passages contained in a conical casing. The latter is enclosed in an outer casing and is provided at the top with an outlet for the purified steam. The inlets to the spirals are closed by ball valves of different weights, the lightest of which opens when only a little steam is passing, the next heavier when more steam is passing, and so on. The edges of the spirals have bent-over channels to facilitate the discharge of the oil or other impurities. The latter pass through openings in the conical casing into a common pipe for each vertical series of openings, and pass thence into the lower part of the space between the conical casing and the outer casing. An electric lamp is fitted in the purified steam outlet, which is also provided with a window so that the extent to which the steam is purified can be observed.—W. H. C.

Dephlegmator. J. E. Mitchell and H. Morfeys, Barnsley. Eng. Pat. 17,507, Dec. 16, 1915.

A DEPHLEGMATOR tray or section for connection with benzol and other stills is shown in plan in the figure. It is constructed with a number of

vapour outlets surmounted by caps or hoods, B, between which baffle plates, C, are interposed to cause the condensed liquid to travel in a circuitous route.—J. E. C.

Refrigerating apparatus: Absorption. F. T. Dunsford, and The Seay Syndicate Ltd., Manchester. Eng. Pat. 17,672, Dec. 17, 1915.

IN absorption refrigerating apparatus of the type in which ammonium nitrate is employed as an absorbent for ammonia. The absorbent is supported upon a corrugated or ribbed surface which contains the pipes or passages for the heating or cooling media; several such surfaces may be arranged in a tier.—W. F. F.

Grinding machinery. T. Breakell, Wirksworth, Derby. Eng. Pat. 102,631, Jan. 11, 1916 (Appl. No. 178 of 1916) and Apr. 6, 1916 (Appl. No. 5089 of 1916).

IN a mushroom type disc mill, a grinding disc is positively driven by a shaft having a universal joint, the disc co-operating with a controlling ring whereby a gyratory motion of the disc is produced. The grinding may be effected partly on the face of the disc and partly on a step or similar arrangement for giving an action corresponding to crushing on the edge of a roll.—J. E. C.

Crushing machinery. R. E. Ellis, London. From R. W. Pringle, Gatooma, South Rhodesia. Eng. Pat. 102,767, Feb. 17 and Aug. 11, 1916 (Appl. Nos. 2406 and 11,385 of 1916).

IN a crushing machine of the type in which the crushing members comprise two concentric rotating millers of inverted conical form, with the annular space between them converging towards the bottom, the lower ends of the millers are cylindrical and the outer miller has a flared extension at the bottom. A second inner conical miller is parallel to the flared end of the outer miller and is adjustable axially so as to vary the discharge space between the millers. The first inner miller may be raised and dropped periodically by a cam operated by the driving mechanism.—W. F. F.

Kiln: Recuperative. R. D. Pike, Richmond, Cal. U.S. Pat. 1,207,209, Dec. 5, 1916. Date of appl., June 1, 1915.

THE exhaust gases from the heating chamber pass through a number of openings in the hearth which register with rows of vertical flues through which the gases pass to a main waste gas flue below. The air to support combustion passes through rows of horizontal flues which alternate with the before-mentioned vertical flues, and heat exchange takes place between the gas and air. The air passes backwards and forwards through groups of horizontal flues and enters an annular flue in the wall of the heating chamber, from which it passes to the burners, which are spaced around the periphery of the heating chamber.—W. H. C.

Centrifugal machine and method. L. P. Sharples, West Chester, Pa. U.S. Pat. 1,207,230, Dec. 5, 1916. Date of appl., Apr. 27, 1915.

A SUSPENDED revoluble bowl is provided with a bottom inlet pipe, upper outlet pipes, and with a steadying device at the bottom. The lower inlet pipe is connected with a tank containing the liquid to be treated, which is drawn into the bowl by the suction produced by the discharge of the separated liquid through the outlet pipe.—W. H. C.

[Graphite] lubricants: Method of making — and products thereof. C. H. Bierbaum, Buffalo, N.Y. U.S. Pat. 1,207,813, Dec. 12, 1916. Date of appl., Apr. 7, 1915.

A WET mass of pulverised graphite freed from impurities is mixed with "petroleum," agitated, and diluted with oil and a solution of "petroleum." —W. F. F.

Graphite crucibles: Composition for preserving — J. B. Carmichael, Assignor to H. J. Harper, Seattle, Wash., U.S. Pat. 1,297,858, Dec. 12, 1916. Date of appl., Jan. 28, 1916.

THE composition consists of a mixture of 18 oz. of pulverised glass, 9 oz. of pulverised pumice, and one quart of a saturated solution of sodium silicate.—W. H. C.

Measuring the flow of fluids: Method and apparatus for — C. W. Humphrey, Chicago, Ill., U.S. Pat. 1,208,159, Dec. 12, 1916. Date of appl., Dec. 17, 1915.

THE flow is measured by observing the differences which occur in the ratio between the expansion of a measured quantity of gas enclosed in a chamber under atmospheric pressure and wholly surrounded by the liquid, the flow of which is to be measured, and the quantity of electric current passed through a resistance heater in the enclosed chamber, when the liquid is at rest and when it is flowing at various speeds.—W. H. C.

Mixing and distributing liquids: Apparatus for — O. Schutz, Assignor to Badische Co., New York, U.S. Pat. 1,208,670, Dec. 12, 1916. Date of appl., Feb. 9, 1916.

A TANK having a front wall lower than the other three walls is divided into compartments by cross walls of less height than the front wall and provided at alternate ends with openings. The liquid is fed into the compartment farthest from the front wall, circulates through the compartments, and is discharged by means of capillary material, which is suspended from a bar above the tank and after dipping into the liquid hangs over the front wall of the tank.—W. H. C.

Dryer: Mechanical — H. L. Julien, Fr. Pat. 480,106, Oct. 29, 1915.

THE material to be dried is moved by a conveyor substantially horizontally through the dryer. Air is drawn in by a fan at the top of the casing, near the outlet for the material, and passes transversely through the material to a heater at the bottom. The air is passed repeatedly through the dryer from top to bottom, being further heated at each stage, till it finally escapes near the inlet for the material.—W. F. F.

Separating uniform or mixed materials according to density or size of particles: Apparatus for — J. Bernard and C. Vibert, Fr. Pat. 480,376, Dec. 2, 1915.

THE material to be separated is fed from the hopper, 26, to the conduit, 11, supplied with water

by the pump, 21, and pipe, 21. The rotating shaft, 4, carries a member, 8, having blades, 9. By suitable adjustment of the relative actions of centrifugal force and of the current of water, material of any desired density or size of particle may be caused to escape by the holes, 12, to the collector, 13. The water passes on to the conduit, 15, and thence to the tank, 20, which supplies the pump. Several similar separating apparatus may be connected in series.—W. F. F.

Pulverisation of solid substances: Process for the — L. Boulade, Fr. Pat. 480,116, Dec. 9, 1915.

THE substance is melted and then sprayed from a nozzle by compressed air or an inert gas, so that it solidifies in a finely divided state.—W. F. F.

Pulsometer: Automatic — for raising liquids, especially acids. J. Cotellet, Fr. Pat. 480,861, Jan. 29, 1916.

LIQUID enters the bottom of a closed vertical vessel through a non-return valve. The top of the vessel is provided with passages communicating with the atmosphere and with a supply of compressed air, the openings being controlled by two vertical glass rods resting on the opposite ends of a pivoted lever at the bottom, so that the rods move simultaneously in opposite directions. A float surrounds the rod controlling the passage to the atmosphere and engages with stops at both ends of the rod. When the float is at the bottom, the atmospheric valve is open and the compressed air valve closed, and liquid fills the vessel and raises the float. When the vessel is full, the atmospheric valve is closed and the compressed air valve opened, so that the liquid is forced out through another pipe at the bottom and the float falls. The cycle is then repeated.—W. F. F.

Furnaces of the tilting type. I. Hall, Birmingham, Eng. Pat. 102,811, Feb. 15, 1916. (Appl. No. 2211 of 1916.)

Impregnating liquids with carbonic acid or other gases: Apparatus for — A. A. Pindstoffe, Copenhagen, U.S. Pat. 1,209,490, Dec. 19, 1916. Date of appl., Sept. 17, 1911.

SEE Eng. Pat. 19,769 of 1914; this J., 1915, 344.

Recovering solvents: Apparatus for — T. Baker, Assignor to E. I. du Pont de Nemours Powder Co., Wilmington, Del., U.S. Pat. 1,209,657, Dec. 26, 1916. Date of appl., Oct. 7, 1912.

SEE Eng. Pat. 10,351 of 1914; this J., 1915, 601.

Spray-producer or atomiser for liquids. D. H. Thomas, Morriston, Wales, A. D. Berk, London, and F. J. Morgan, Swansea, U.S. Pat. 1,210,232, Dec. 26, 1916. Date of appl., Dec. 29, 1915.

SEE Eng. Pat. 608 of 1915; this J., 1915, 1132.

Separating substances of different specific gravities, such as fine coal or ores and the like: Apparatus for — J. M. Draper, Manchester, U.S. Pat. 1,210,916, Jan. 2, 1917. Date of appl., Jan. 21, 1916.

SEE Eng. Pat. 1849 of 1915; this J., 1915, 1196.

Separation of liquids by centrifugal force: Process and apparatus for — L. P. Sharples, Fr. Pat. 480,726, Jan. 21, 1916. Under Int. Conv., Apr. 27, 1915.

SEE U.S. Pat. 1,207,230 of 1916; preceding.

Apparatus for continuous distillation. Fr. Pat. 480,558. See XVIII.

IIA.—FUEL; GAS; MINERAL OILS AND WAXES.

Ammonia recovery [from coal gas] and intensive scrubbing. W. S. Blauvelt. Gas Record, 1916. Gas J., 1917, 137, 63—64.

THE factors operative in washing gas by water for ammonia recovery are considered, and it is pointed out that an equilibrium between ammonia in the gas and in the wash liquor may limit the effectiveness of the process. Washers are classified under four types:—1. Washers in which the gas bubbles through the wash liquor. These may cause considerable back pressure. 2. Tower scrubbers, up which the gas ascends once meeting a descending stream of wash liquor. Time and area of contact are increased by fillings of coke, tiles, or wooden grids. The cost is relatively low, and back pressure is small. The large size required renders this type unsuitable for large works. 3. Mechanical washers containing moving internal parts which effect good contact between gas and liquor. They are usually multi-stage with gas moving counter to the liquor. 4. "Intensive scrubbers," comprising a number of towers or compartments in series, with grid fillings. The liquor passes repeatedly down each tower before proceeding to the next. Gas and liquor flow in counter currents. Types 3 and 4 are more adapted for use in larger works, and it is considered that the "intensive scrubber" has the advantage over the mechanical washer. In the latter a large portion of the contact surface is always submerged and out of action, in the former it is all in action. Installation costs, and over a long term of years maintenance costs also are lower, and ground space less, while the "intensive scrubber" also works better under overload conditions.—H. J. H.

Petroleum Supplies Branch of the Ministry of Munitions.

THE Minister of Munitions has established a Petroleum Branch in the Ministry, to be known as the Munitions Petroleum Supplies Branch, to deal with questions of the provision and distribution of petroleum and similar mineral oils for the purposes of the Ministry of Munitions. Mr. E. Houghton Fry will act as Director of the Branch. In connection with the investigation and development of hitherto unproved home sources of supply of mineral oils, the Minister will have the advantage of the services of Sir Boverton Redwood as Director of Munitions Petroleum Research. Sir Boverton Redwood will have charge of the Research Section, including the development of the British sources of supply. Professor John Cadman, C.M.G., President of the Institute of Petroleum Technologists, has assisted in the organisation of arrangements with the Scottish shale distilleries during the war, with a view to a considerable increase in their output. Sir George Beilby is also assisting in an advisory capacity.

Gas-oils: Cracking of— in various atmospheres. R. C. Downing and E. F. Pohlman. Amer. Gas Institute. Gas J., 1917, 137, 24—26.

THE atmospheres used were nitrogen, carbon dioxide, carbon monoxide, hydrogen, methane, blue gas, and a mixture of blue gas with 10 and 20% of steam respectively. The effect of each diluent on candle-power of the gas, candles per gallon, B.Th.U. per gallon, and the production of gas, tar, and carbon was studied. With nitrogen the calorific power of the gas per gallon of oil was 97,000 B.Th.U. at 1350° F. (about 730° C.). This is slightly better than is obtained in atmospheres of carbon monoxide, carbon dioxide, and methane, and lower than in hydrogen or blue gas. The

amount of tar and carbon produced was considerable, as is usually the case in inert atmospheres. The yield of oil-gas by weight was rather low. In an atmosphere of carbon dioxide the volume of the gas made was over 60 cu. ft. per gallon of oil, and it contained much hydrogen and methane. The production of carbon was much increased. The reaction $2\text{CO}_2 + \text{C}_2\text{H}_4 = \text{CO} + 2\text{H}_2$ probably occurs to a slight extent. With hydrogen, gas of high calorific power tends to be produced, owing to the production of saturated compounds. There is a decrease in the formation of tar and carbon. The production of illuminants is low; apparently some of the unsaturated compounds are hydrogenated. Methane acts very much like an inert atmosphere; much less methane is actually produced from the oil, but the production of hydrogen is larger, due probably to the decomposition of the methane. The effect of blue gas was studied in some detail. The conclusion is reached that no advantage is to be gained over blue gas by the use of any of the above-mentioned atmospheres alone. Blue gas gives much better candle-power results than either hydrogen or carbon monoxide. Tar formation is lowered and the deposition of carbon is about the average. Steam lowers the candle-power and candles per gallon, but raises the B.Th.U. per gallon of oil, possibly due to formation of hydrogen by partial decomposition of the steam. The appearance of the flames when the gas formed in the various atmospheres was burned in a Bray burner is also described. With carbon monoxide great loss of candle-power was noticed, due to the large proportion of carbon monoxide in the finished gas. The B.Th.U. results were the lowest obtained with any atmosphere except from oil used alone with a much longer time of contact. More tar was produced with carbon monoxide than in any other atmosphere. Carbon monoxide moreover seems to prevent the decomposition of the "illuminants." (See also this J., 1916, 917.)—F. C.

Combustion methods for use in the laboratory. [Determination of sulphur.] Hewett. See XXXII.

PATENTS.

Gas producers. F. Thuman, London. Eng. Pat. 102,597, Sept. 16, 1916. (Appl. No. 13,178 of 1916.)

THE bottom of the producer is provided with a base-plate, *c*, rotated by bevel gearing, *g*, and carrying a grate having water-circulating channels,

k. Cooling water is supplied by the pipes, *m, m'*, and withdrawn by the pipes, *n', n*. Steam is supplied through the sprayer, *v*, and passes with air to the fire through the openings, *l*. The water pipes are protected from the hot ashes by a surrounding sleeve carried by the stuffing-box, *o*.

Solidified hydrocarbons: Treatment of —for the manufacture of combustible blocks. A. C. B. Webb. Fr. Pat. 480,347, Nov. 29, 1915. Under Int. Conv., Oct. 30, 1915.

DEHYDRATED calcium sulphate, clay, or earth is mixed with wax, heavy mineral oil, or heavy vegetable oil to form a porous combustible mass which may be ignited by pieces of celluloid or cotton waste.—J. E. C.

Coal gas: Apparatus for manufacture of —. The Riter-Conley Manufacturing Co. Fr. Pat. 480,531, Dec. 6, 1915.

SEVERAL gas retorts are connected to a common stand-pipe, to secure a uniform temperature high enough to fix the lighter hydrocarbons in the gas (about 1000° F., 540° C.). The stand-pipes communicate with short mains, in which the gas is cooled by liquid sprays to about 110° to 125° F. (43° to 52° C.). The gas then passes to the general purification plant. Means of access to the stand-pipes and short mains are provided.
—J. E. C.

Gas: Manufacture of —. L. D. Carroll. Fr. Pat. 480,535, Dec. 7, 1915.

IN the manufacture of carburetted water-gas or similar gases, the primary and secondary air are controlled so as to give a constant volume of air per unit of time. The regulation may be effected by governors acting on the source of power driving the air blower and controlled by the differential pressure produced by a Venturi meter, perforated diaphragm, or Pitot tube.
—J. E. C.

Gas: Manufacture of —. L. D. Carroll. Fr. Pat. 480,536, Dec. 7, 1915.

IN a gas-producing system in which a gas with increasing content of carbon monoxide is produced, the secondary air is regulated in proportion by a throttle-valve in the air conduit and controlled by the rise and fall of a governor bell. The bell is actuated by a three-way cock alternately connecting the contents with the air conduit and the atmosphere. Means are also provided for counteracting the effect of increased pressure in the air conduit.—J. E. C.

Coal gas: Apparatus for manufacture of —. L. D. Carroll. Fr. Pat. 481,095, Mar. 1, 1916.

IN a vertical retort system for the manufacture of coal gas, one of the retorts communicates directly with a producer and supplies the necessary coke. Means are provided for regulating the pressure in this retort and in the producer to prevent the producer gas passing into the coal gas retort.—J. E. C.

Hydrocarbons: Extraction of —from coal gas. G. E. Darier. Fr. Pat. 479,997, Jan. 12, 1915.

HYDROCARBONS of the benzene and ethylene series are recovered by cooling coal gas to a temperature low enough to precipitate these bodies in a solid or liquid state. A recuperative system is provided by using two coolers alternately, in one of which the hydrocarbons are precipitated in a solid state, whilst in the other the solid products are liquefied by passing the uncooled gas through the chamber. The solid

products may also be extracted by solvents, or solvents solidifying with difficulty may be introduced prior to cooling. The hydrocarbons may be separated at higher temperatures by introducing porous substances, such as animal charcoal, coconut fibre, etc., whilst benzene compounds may be selectively separated, leaving ethylene compounds in the coal gas.—J. E. C.

Gaseous mixtures: Proportioning of —. A. C. Ionides, jun., London. Eng. Pat. 17,670, Dec. 17, 1915.

THE proportions of the constituents of a self-burning gaseous mixture are adjusted by observation of the lighting effect produced by combustion with an incandescent mantle under regulated pressure conditions. The illumination may be compared with a standard source of light or with a guide light using a mixture of known proportions.—J. E. C.

Producer-gas: Process for producing a diffused flame with —. H. L. Doherty, New York. U.S. Pat. 1,206,821, Dec. 5, 1916. Date of appl., May 15, 1911. Renewed Mar. 11, 1916.

THE flame is regulated to produce a uniform heating effect by mixing from 5 to 100% of combustion gases with the producer gas and burning it in a furnace chamber with pre-heated air, so that a slow burning flame of moderate temperature fills the chamber.—W. F. F.

Hydrocarbon oils: Method of dehydrating and refining —. E. I. Dyer, Oakland, Cal. U.S. Pat. 1,207,381, Dec. 5, 1916. Date of appl., Mar. 5, 1913.

THE oil is made to flow in a thin layer over heated surfaces in a closed vessel, and, after removal of the lighter vaporised portions, it is conducted, without cooling, into a second closed vessel, where it is again made to flow circuitously over heated surfaces at a higher or lower temperature and pressure than in the first vessel. Outside heating is used for one of the vessels, and the vapours generated therein are conducted through the other vessel as a heating medium for the oil. The oil in each vessel is agitated during the heating, and means are provided for condensing the vapours which have been used for heating one of the vessels.—C. A. M.

Petroleum: Apparatus for converting heavy products obtained from —. Process for the conversion of heavy products of petroleum. P. Roth and M. E. Venturino, Buenos Aires, Argentina. U.S. Pats. (A) 1,208,214 and (B) 1,208,378, Dec. 12, 1916. Date of appl., Oct. 16, 1916.

(A) PETROLEUM products are successively heated in a series of connected boilers, each of which is provided with means for discharging and condensing the vapours formed in the distillation. The heavy or middle hydrocarbons thus obtained are separated from water and impurities, and are sprayed under pressure into the vapour space of the lowest or converting boiler, which is also connected with a condenser to receive the vapours formed in the process. (B) Petroleum residues, asphalt, oils, or crude petroleum are sprayed into the vapour space of a still above a layer of similar material which has been heated to a temperature above that required to "crack" the heavy hydrocarbon or crude petroleum to be treated, whereby partial vaporisation of the sprayed liquid is effected, while the greater proportion of the volatilisation and cracking occur when the liquids come into contact. The resulting vapours are condensed.—C. A. M.

Petroleum oils; Process and apparatus for transforming heavy—into light oils. Simplex Refining Co. Fr. Pat. 480,447, Nov. 8, 1915.

HEAVY petroleum oil is made to circulate, with or without pressure, in a continuous cycle, *e.g.*, through serpentine tubes, which are heated to the "cracking" point of the oil, and means are provided for the continuous withdrawal of the resulting vapour and the addition of fresh oil to keep the circulating oil at a constant volume. A portion of the condensed light vapour is injected into the residue when it returns to the heating vessel. Advantages claimed for the process are regularity in working, and the prevention of overheating and formation of carbonaceous and viscous deposits within the tubes.—C. A. M.

Chemical reactions; Producing—in a single [gaseous] phase. [Cracking hydrocarbons.] Synthetic Hydro-Carbon Co. Fr. Pat. 480,653, Jan. 11, 1916.

A VERTICAL tube of refractory material heated electrically by a surrounding coil, is provided at the top with a plug of loose refractory material through which liquid hydrocarbon is supplied to be gasified and then cracked. The products, which vary with the temperature, pressure, and the rate at which the gasified material flows through the heated zone, pass through a condenser to a liquid-collecting vessel having a pipe leading to a pump for withdrawing the gas at the top. Light hydrocarbon oils are produced at temperatures of 600°–900° C. and pressures about 6 atmospheres. Permanent gases are produced in large proportion at a pressure of about 0.28 kilo. per sq. cm.—W. F. F.

Motor spirit suitable for high-speed internal combustion motor engines; Process of producing—. Hall Motor Fuel, Ltd. Fr. Pat. 481,066, Feb. 25, 1916.

THE fraction of kerosene oil boiling up to about 220° C., which must be practically free from petroleum spirit, is forced through very narrow interstices at a high pressure (70 to 200 kilos. or more, per sq. cm.), in the presence of hydrogen or a hydrocarbon gas, and at a temperature not exceeding 100° to 120° C. or that of the initial boiling point of the liquid. The resulting product burns much more rapidly than kerosene oil in motor engines.—C. A. M.

Petroleum or other hydrocarbons; Apparatus for the continuous fractionation and dephlegmation of the products of the distillation of— or of a mixture of volatile liquids, including products of the distillation of shale, coal, or both. H. L. Allan. Fr. Pat. 481,134, Mar. 8, 1916.

THE vapour from the first distillation is made to pass downwards through vertical tubes of a dephlegmator, which are exposed to the air, and may also be cooled by water which trickles over them and is collected in a tray. The condensed liquid which collects in the vessel below the tubes may be redistilled by means of a steam coil or the like, and the resulting vapour passed upwards through other vertical tubes into a box at the top connecting the series of tubes, and thence to a water-condenser. In this process the latent heat of the condensed fractions is utilised in the redistillation of the portions of lower boiling point. The fractions collected at each stage are of uniform quality.—C. A. M.

Coal gas retorts; Charging machines for use in operating—. A. E. White, London. From Riter-Conley Manufacturing Co., Leedsdale, Pa., U.S.A. Eng. Pat. 102,839, Jan. 19, 1916. (Appl. No. 857 of 1916.)

Carbon from [oil-] gas refuse; Method of producing granular—. R. D. Pike, San Francisco, Cal. U.S. Pat. 1,207,694, Dec. 5, 1916. Date of appl. Apr. 1, 1916.

LAMPBLACK from the refuse of oil-gas manufacture is heated to a relatively low temperature to expel water, and is then mixed with oil-gas tar to form a semi-plastic mass which is pressed into cakes. The cakes are heated to a high temperature to expel all volatile products and the residue finely ground and subjected to magnetic separation.—W. F. F.

Are light carbons, and method of manufacturing the same. R. D. Pike, Richmond, Cal., U.S.A. Eng. Pat. 102,645, Feb. 21, 1916. (Appl. No. 2541 of 1916.)

IN the production of are light carbons from the so-called lampblack refuse from the manufacture of illuminating gas from crude petroleum, the tar and soluble ash are removed from the refuse by washing. Volatile hydrocarbons are then removed by roasting, and the resulting product ground and incorporated with a suitable flux (such as boric acid) to produce a plastic body. Carbons are formed from the plastic mass in the usual manner.—J. E. C.

Arc device; Inclosed— and method of operating the same. G. M. J. Mackay, Schenectady, N.Y., Assignor to General Electric Co., U.S. Pat. 1,208,597, Dec. 12, 1916. Date of appl. Oct. 30, 1915.

A REFRACTORY cathode, such as tungsten, with a melting point exceeding 2000° C., is adapted to co-operate at incandescence with an anode within a sealed envelope, and the latter is filled with a monatomic gas, such as argon, with a pressure, at the operating temperature, of several millimetres of mercury, the gas being inert with respect to the electrodes and suppressing the electrical disintegration of the cathode. A drying material, inactive with respect to argon, is employed to remove the water vapour emitted from the electrodes and the walls of the envelope. The drying material is liberated in the form of vapour, by the operation of the arc, and forms compounds of negligibly low vapour pressure by combination with the water vapour.—B. N.

[*Tungsten*] *metal-filament manufacture.* O. Oberländer, London, Assignor to General Electric Co., U.S. Pat. 1,208,629, Dec. 12, 1916. Date of appl. Nov. 27, 1911.

A PLASTIC mass, for the manufacture of tungsten filaments, is formed by treating tungsten hexachloride with methylated ether, and then evaporating the resulting product to a paste of suitable consistency for further treatment.—B. N.

Electric incandescence bodies; Process for manufacturing—. C. O. Bastian, London, U.S. Pat. 1,209,247, Dec. 19, 1916. Date of appl. Sept. 21, 1914.

III.—TAR AND TAR PRODUCTS.

Aromatic base oil; Cracking of—. The temperature factor at constant rate under pressure. G. Egloff and R. J. Moore, J. Ind. Eng. Chem., 1917, 9, 10-12.

For the production of benzene and toluene from an aromatic base oil, the best results were obtained with solvent naphtha. The oil was passed through a steel tube, 11½ ft. long by 8 in. in diameter, at a pressure of 11 atmos. and at the rate of 15 galls. per hour, the temperatures used being 500°, 550°, 600°, 650°, 700°, 750°, and 800° C. In the recovered oil the maximum yield for benzene was 42.5% at 800° C., and for toluene 39.9% at 750° C.; or, calculated on the basis of the solvent naphtha used, 15.9% for benzene and 20.6% for toluene. The following table shows the maximum yields obtained under comparable conditions from a paraffin base oil and a naphthene base oil:—

	Paraffin oil.		Naphthene oil.		Aromatic oil.	
	by vol.	°C.	by vol.	°C.	by vol.	°C.
Benzene	6.6	750	7.2	650	15.9	800
Toluene	1.5	650	6.0	650	20.6	750

The course of the decomposition effected by the cracking of the solvent naphtha is of the same kind as the reaction produced by aluminium chloride on alkyl derivatives of benzene, which are converted successively into lower alkyl derivatives, toluene, and benzene (Ber, 1884, 17, 2816; this J., 1885, 270). The yield of recovered oil decreased from 100% at 500° C. to 98% at 650° and to 37.3% at 800° C. The greatest decomposition (25%) took place between 700° and 750° C. The sp.gr. of the recovered oils increased from 0.868 at 500° C. to 0.989 at 800° C., which indicated the formation of polycyclic aromatic hydrocarbons of high molecular weight.

—C. A. M.

Trinitrobenzene; Additive compounds of—. J. J. Sudborough, Chem. Soc. Trans., 1916, 109, 1339-1348.

POLY-NITRO compounds of the aromatic series possess the property of forming additive compounds with aromatic hydrocarbons, amines, phenols, phenolic ethers, and sulphur compounds. A large number of additive derivatives of *s*-trinitrobenzene have been prepared and analysed. In the majority of cases the compound is obtained by mixing theoretical proportions of the components and crystallising from a suitable solvent, usually alcohol, but occasionally benzene. In other cases the compound was only obtainable by using an excess of the hydrocarbon or base over the amount calculated to form the trinitrobenzene derivative. As a rule the colour of the additive compounds with hydrocarbons is not so marked as that of the corresponding amino- or hydroxy-derivatives; the colour of the hydrocarbon additive compounds is usually yellow, but anthracene gives a bright red compound. It would appear that the formation of these compounds is due to latent valencies of the nitro-groups and of the aromatic residues of the hydrocarbon; the hydroxy-, alkoxy-, amino-, and alkylamino-groups act mainly as auxochromes and tend also to increase the stability. As regards the combining proportions, it would appear that the number of trinitrobenzene molecules combining varies with the number of independent aromatic nuclei in the other component; in this connection, however, a condensed system of several benzene or benzene and heterocyclic rings counts as a single nucleus. Compounds in equimolecular proportions are formed with naphthalene, anthracene, phenanthrene, aniline, etc. Compounds of two mols. of trinitrobenzene and one mol. of the substance are formed with stilbene, diphenylamine, etc. There are, however, exceptions to the rule, and several substances form two types of additive compounds containing one and two mols. of trinitrobenzene respectively. Quite a number of substances containing two or more independent aromatic nuclei combine in equimolecular proportions; in a few cases one mol. of trinitrobenzene combines with two of the substance.

—J. F. B.

s-Trinitrobenzene; Additive compounds of— with amino-derivatives of complex aromatic hydrocarbons. S. T. Cadre and J. J. Sudborough, Chem. Soc. Trans., 1916, 109, 1349-1354.

As a rule the additive compounds (see preceding

abstract) obtained from naphthalene derivatives are more stable than those derived from corresponding benzene compounds. A series of compounds has been prepared from amino derivatives of phenanthrene, anthracene, acenaphthene, and fluorene. With the exception of aminofluorene all these compounds were formed by the union of equimolecular proportions of trinitrobenzene and the base. In this series, the colours of the additive compounds are relatively deep, being, as a rule, either black or deep brown, whereas those of the naphthalene series are mainly orange-yellow or red. The compounds are comparatively stable and can be crystallised from most solvents, but determinations of molecular weights showed that, in dilute benzene solution, dissociation into the components is almost complete. These compounds, on the whole, resemble the additive compounds from the naphthylamines, but several of them appear to be incapable of yielding acetyl derivatives.—J. F. B.

Benzoyl chloride; Catalytic decomposition of —. A. Mailhe and F. de Godon. Bull. Soc. Chim., 1916, 19, 419—452.

BENZOYL chloride when passed with a current of hydrogen over finely divided nickel at 270° — 280° C. furnishes to the extent of about 50% a mixture of benzene and toluene, and about 40% of diphenyl. The mechanism of the formation of the latter is obscure, but it appears to be conditioned by the formation of nickel chloride on the surface of the catalyst, and is not suppressed even when an excess of hydrogen is employed. With copper as catalyst benzoyl chloride is decomposed up to about 40% into benzoic anhydride, the remainder being unchanged. A similar conversion occurs at 420° — 450° C. with the chlorides of barium and thorium, with simultaneous deposition of carbon on the catalyst, and formation of carbon monoxide and hydrogen chloride. The manner of formation of the anhydride remains uncertain.—G. F. M.

Friedel-Crafts reaction; Observations on the —. [Decomposition of polyalkylbenzenes.] E. Brätker and O. M. Halse. Bull. Soc. Chim., 1916, 19, 411—449.

A REVERSAL of the Friedel-Crafts reaction can in general be brought about with more or less facility by the action of aluminium chloride on the alkylbenzene in presence of a large excess of benzene. In the case of the xylenes alone, this reaction does not succeed, but when polyethyl-, isopropyl-, butyl-, and amylbenzenes were boiled with aluminium chloride in presence of ten times their weight of benzene, quantities of the monoalkylbenzene, varying in each case were formed according to the scheme:—

Of the greatest interest however was the formation in excellent yield of toluene and cumene from cymene, which is available in large quantities as a by-product of the sulphite-cellulose process. Ninety grms. of cymene in 900 grms. of benzene gave, on boiling for 10 hours with 4.5 grms. of aluminium chloride, a yield of 11 grms. of toluene and 68 grms. of cumene, corresponding to 80% of that theoretically possible, leaving a residue of only 3—4 grms. of gummy material. The polyhalogen derivatives of benzene could not be decomposed by the action of aluminium chloride and benzene in this manner.—G. F. M.

PATENTS.

Aromatic hydrocarbons: Improving the colour and odour of crude —. J. M. Weiss, Assignor to The Barrett Co., New York. U.S. Pat. 1,206,962, Dec. 5, 1916. Date of appl. Jan. 22, 1913.

THE oil to be purified is intimately mixed with an aqueous solution of a metallic salt, such as copper sulphate, in the proportion of 1 to 3 lb. of the hydrated salt to 100 galls. of oil, and the reaction allowed to proceed at a temperature below the point at which distillation of the volatile ingredients of the mixture occurs. The mixture is settled, the aqueous liquor drawn off, and the remaining oil distilled.—B. N.

Sulphonic acids: Process of manufacturing sodium salts of —. A. P. Sachs and O. Byron. Carnegie, Pa. U.S. Pat. 1,207,798, Dec. 12, 1916. Date of appl. Apr. 6, 1916.

A MIXTURE of a sulphonic acid forming a water-soluble calcium salt, sulphuric acid, and water is neutralised with lime to obtain a mixture of calcium sulphate and the calcium salt of the sulphonic acid. This mixture is agitated, without previous filtration, with sodium sulphate, and then filtered.—F. W. A.

Aromatic amino-hydroxy compounds: [Electrolytic] manufacture of —. O. Inrady, London. From Soc. of Chem. Ind. in Basle, Switzerland. Eng. Pat. 18,981, Dec. 28, 1915.

IN the electrolytic reduction of aromatic nitro-compounds, the formation of the amino-hydroxy compound is favoured and that of the amine reduced, by the use of a cathode of two or more metals. The cathode is obtained either by the use of a suitable alloy, the surface of which remains of practically constant composition during the reaction, or by making the cathode of one metal and placing the other, either as such or as salt, in the electrolyte, or by using an indifferent substance such as carbon and depositing the metals thereon during the electrolysis. It is possible to reduce the amount of acid to very little more than is necessary to combine with the base which is formed. Details are given of the reduction of nitrobenzene using a copper cathode, with lead, or lead and arsenic, in the electrolyte, and with a lead cathode with bi-smuth in the electrolyte. Other suitable combinations of metals are copper with mercury, and copper with tin and arsenic. A plain lead cathode under these conditions would give *p*-aminophenol and aniline in the proportion of about 2 to 3, while this method gives them in the proportion of 5 or 6 to 1.—B. V. S.

Monochlorobenzene: Manufacture of —. G. Contagne. Fr. Pat. 480,151, Feb. 17, 1915.

MONOCHLOROBENZENE is formed by the action of chlorine on benzene, in the presence of a catalyst such as iron, the process being so conducted that strong chlorine vapour comes into contact only with fresh benzene. A stream of benzene flows through a vertical series of basins exposed to a stream of chlorine passing in the same direction as the benzene. The formation of higher chlorine compounds is further reduced by mixing with the chlorine vapour hydrochloric acid previously formed by the reaction. Cooling appliances are used for maintaining the benzene at a temperature of 15° C.—B. V. S.

Binding compound from coal tar, &c., and process of making same. A. C. Evans, Hampton Wick, and P. J. Mitchell, London. U.S. Pat. 1,209,692, Dec. 26, 1916. Date of appl. Sept. 7, 1915.
